Part 2:
Detailed results for sub-domains and individual countries

Legal notice:

Neither the European Commission nor any person acting on behalf of the European Commission is responsible for the use that might be made of the following information.

The opinions expressed are the view of the authors and their sole responsibility and not necessarily those of the European Commission or any of its services.

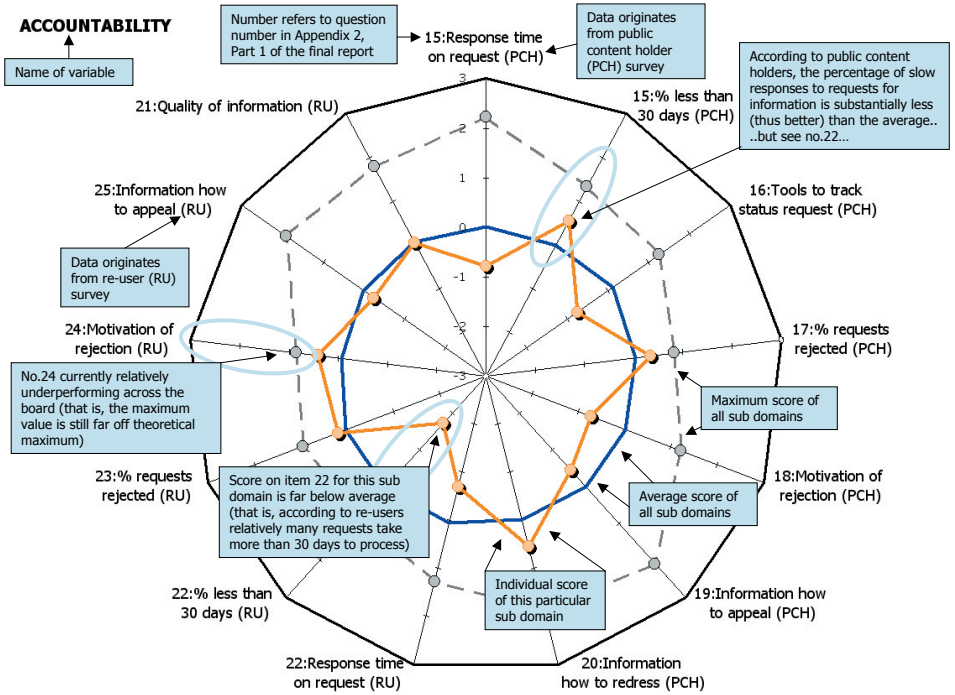

Figure 1: Example radar chart

Presentation and interpretation of results

The current document contains an overview of the data gathered in the MEPSIR study for the individual sub-domains and individual countries. The full set of source data will be delivered separately.

It should be noted that the study focused on the main categories of public sector information, covering areas that are considered to be the most valuable. Furthermore, some domains were left out, such as scientific information and cultural information, which are outside the scope of the Directive.

The table shows three kinds of totals: the score of an individual country or subdomain on a particular item, and the average value ('AVR all') and median value ('MED all') of all countries or subdomains. As a rule of thumb, if the average and median values are close, the average value can be considered as a robust value. If the average and median are fairly different (and the standard deviation usually relatively big) the median is probably a better representation of the 'true' average of the data set[1].

The results of the two cross-sections are shown in disaggregated form, that is, per individual country and individual sub-domain. The results are presented in a standard format, with four radar charts to the left and a comprehensive table to the right.

The table shows all results for all relevant items grouped per variable (with the obvious exception of 'Availability'). The last variable (d. under 'Economic performance') is discussed in more detail in chapter 10 of Part 1 of this report. Unlike the other variables, the percentages in the column 'AVR all' refers to the share of GDP, not to the average. The first two numbers are directly based on estimates from respondents, the last number on the proxies calculated in the second part of chapter 10[2].

The table has absolute scores, either as 'real' numbers (e.g., average response time on request for information) or percentage on a standard scale from 0 to 100%[3]. In the latter case, higher percentages always represent higher scores. For instance, a 90% score on 'non-discrimination' represents more cases of non-discrimination (hence less cases of discrimination, sic!) than a 50% score.

The radar charts show the same items per variable (plus a number of additional items) but here the scores have been standardized to enable comparison of the various different distributions[4]. The blue polygon in the middle of the radar chart represents the average of all scores. Similar to the original scores in the table, higher scores are higher on the scale – closer to the border of the chart – than lower scores. Thus scores outside the blue circle are "better than average", scores inside the blue circle "lower than average". In addition to the average, the maximum score for each item is shown. This is the dotted polygon that surrounds the blue polygon. The surface inside the dotted line shows the theoretical space of maximum values ('top scores') at this moment. In a follow-up measurement, this space will most likely be expanded. This means that similar absolute scores actually mean a relative decline compared to the previous situation. A drawback of standardising scores is that most scores tend to cluster around the average if there are one or two extreme values in the data set. In other words, if the maximum value on a certain item is already very high (the dotted line touches the boundary of the graph), many countries and/or sub-domains will have scores that lie close to the average (the blue polygon in the graph). This does not necessarily imply that the country and/or sub-domain really have an average score, only that the difference between the maximum score and the other scores is relatively big. If the extreme high score would be removed, the scores of the other countries and/or sub-domains would show much more variation around the average again.

[1] Since the median in such cases is usually (much) lower than the average the value represents the cautious estimate.

[2] 'Estimate of overall PSI market size based on turnover', especially Table 2. Because the calculation of the total market size per country is based on GDP the share of GDP is the same for all countries (0.25%)

[3] The reference point is the maximum score of the data set. The score of a country or sub-domain is divided by the maximum score of all countries or sub-domains. Hence when the score of a country or sub-domain is equal to the maximum score, the percentage is 100%. If the score is 1/10 of the maximum, the score is 10% etceteras.

[4] Although the original scores might have the same scales (at least the percentages do) the underlying distribution might be entirely different. For instance, nearly all countries have very high scores (>95%) on the item 'Response within 30 days'. On the other hand, scores on the item 'Information related to legal remedies > Assessment by clients' are much more evenly distributed across the entire 0-100% range. All these different scales are made comparable by converting all original scores to Z-scores, that is, to put the average of the distribution to zero and the standard deviation to 1 (in formula: Z = (original score – AVR) / STDEV.
