The apparent labour productivity of the EU-27's leather and related products manufacturing sector in 2009 was EUR 23 thousand per person employed. This was the second lowest level of apparent labour productivity among the manufacturing NACE divisions in 2009 (higher only than the manufacture of wearing apparel, Division 14) and was half the manufacturing average (EUR 46 thousand per person employed). In line with this low apparent labour productivity ratio, the EU-27's leather and related products manufacturing sector also recorded a low level of average personnel costs, EUR 18.2 thousand per employee in 2009. This was also the second lowest value across the manufacturing NACE divisions, and was a little more than half the manufacturing average (EUR 34.5 thousand per employee). As for wearing apparel manufacturing, these relatively low values may reflect an above average incidence of part-time work, as both of these indicators are compiled on a per head basis using a simple head count. In contrast, the wage-adjusted labour productivity ratio combines the two previous indicators in percentage terms; and shows the extent to which value added per person employed covers average personnel costs per employee. This latter ratio was 127.1% for the EU-27's leather and related products manufacturing sector in 2009, 5.0 percentage points below the manufacturing average (132.1%).

The gross operating rate for the EU-27's leather and related products manufacturing sector in 2009 shows that the gross operating surplus was 7.0% of turnover, the same rate as recorded for manufacturing as a whole, and therefore below the non-financial business economy average (9.7%).

Sectoral analysis

The manufacture of footwear (Group 15.2) was the largest of the two subsectors within the EU-27's leather and related products manufacturing sector. Footwear manufacturing enterprises made up 58.7% of the enterprise population, and they generated 57.1% of sectoral value added and employed close to 70% of the sectoral workforce. The remaining subsector, tanning and dressing of leather, dressing and dyeing of fur, and the manufacture

of other leather products such as luggage, handbags, saddlery and harnesses (Group15.1; hereafter referred to as leather and fur processing) accounted for the remainder.

Apparent labour productivity per person employed varied greatly between the two leather subsectors in the EU-27, ranging from EUR19 thousand for footwear manufacturing in 2009 to EUR33 thousand (2008 data) for the smaller subsector of leather and fur processing. Equally, average personnel costs per employee were much lower for footwear manufacturing (EUR15.1 thousand) than they were for the leather and fur processing subsector (EUR24.9 thousand, 2008 data). The wage-adjusted labour productivity ratio was more balanced, with the leather and fur processing subsector recording a ratio of 132.2% in 2008 and the footwear manufacturing subsector a ratio of 125.7% in 2009. A direct comparison of the two subsectors using 2008 data shows that the footwear manufacturing subsector had notably lower apparent labour productivity and average personnel costs than the leather and fur processing subsector, but its wage-adjusted labour productivity ratio in 2008 was higher, standing at 135.6%.

Country analysis

As for the manufacture of [textiles](#) (Division13) and wearing apparel, the largest Member State (in value added terms) in the EU-27's leather and related products manufacturing sector in 2009 was Italy. Italy's share of the EU-27's wearing apparel manufacturing sector was 44.6% in 2009, the highest share for Italy in any of the non-financial business economy NACE divisions (with data available) in 2009. Italy's share of EU-27 value added ranged from 44.3% for the leather and fur processing subsector to 44.9% for footwear manufacturing. The only other Member States with a double-digit share of value added in the EU-27's leather and related products manufacturing sector in 2009 were France (13.9%) and Spain (10.1%). Nevertheless, the 5.9% share of EU-27 value added recorded for Portugal in this sector was the highest share for Portugal in any of the non-financial business economy NACE divisions (with data available) in 2009. In terms of the workforce, the Italian share was slightly smaller, 33.4% of the EU-27 total, while Romania (14.1%) and Portugal (10.3%) both contributed larger shares of those employed within the EU-27 than either Spain (7.9%) or France (6.0%, based on employees).

The relative importance of the leather and related products manufacturing sector in value added terms was highest in Portugal, Italy and Romania where it accounted for 0.7% or more of non-financial business economy value added, and this share was 0.5% in Slovakia. In many Member States this sector accounted for a very small share of non-financial business economy value added, less than 0.1% in the Czech Republic, Lithuania, Germany, the Netherlands, the United Kingdom, Cyprus, Sweden, Latvia, Ireland and Luxembourg, as well as in Switzerland. In the largest subsector, namely footwear manufacturing, Portugal, Romania, Slovakia, Italy and Bulgaria were the most specialised Member States, whereas Italy was by far the most specialised Member State for leather and fur processing, followed at some distance by Slovenia and France.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the leather and related products manufacturing sector in the EU, as covered by NACE Rev.2 Division15. This division includes the dressing and dyeing of fur and the transformation of hides into leather by tanning or curing, as well as fabricating leather into products for final consumption. The manufacture of footwear includes footwear for all purposes, of any material, by any process, including moulding. It also includes the manufacture of similar products from other materials (imitation leathers or leather substitutes), such as rubber footwear, textile luggage and so on.

This NACE division is composed of two groups:

- the tanning and dressing of leather, dressing and dyeing of fur; the manufacture of other leather products such as luggage, handbags, saddlery and harnesses (Group15.1);
- the manufacture of footwear (Group15.2).

Note that the manufacture of wooden, rubber or plastic shoe parts is excluded (and classified as part of [wood](#) , [rubber or plastic](#) manufacturing). Leather wearing apparel, gloves and hats are classified as part of the [manufacture of wearing apparel](#) (Division14).

Table 4b: Key indicators, manufacture of machinery and equipment n.e.c. (NACE Division28), 2009 - Source: Eurostat (sbs_na_ind_r2)

Main statistical findings

Structural profile

There were 96 thousand enterprises operating with machinery and equipment manufacturing (Division28) as their main activity in the EU-27 in 2009. Together they employed 2.92 million persons, equivalent to 2.2% of all persons employed in the non-financial business economy (Sections B to J and L to N and Division95) and 9.5% of the manufacturing (Section C) workforce. They generated EUR 150000 million of value added which was 2.7% of the non-financial business economy total and 10.7% of the manufacturing total.

In employment terms, the EU-27's machinery and equipment manufacturing sector was the third largest manufacturing NACE division in 2009 after food products manufacturing (Division10) and the manufacture of fabricated metal products (Division25), while the machinery and equipment manufacturing sector had the second highest level of value added, after food products manufacturing.

The apparent labour productivity of the EU-27's machinery and equipment manufacturing sector in 2009 was EUR 51 thousand per person employed, above the non-financial business economy average of EUR 41.6 thousand per person employed and the manufacturing average of EUR 46 thousand per person employed. Furthermore, average personnel costs within the EU-27's machinery and equipment manufacturing sector were also relatively high, EUR 41.7 thousand per employee, compared with EUR 30.0 thousand per employee on average in the non-financial business economy and EUR 34.5 thousand per employee on average for manufacturing. The combination of these two indicators produces the wage-adjusted labour productivity ratio which stood at 123.6% for the EU-27's machinery and equipment manufacturing sector in 2009, around 15 percentage points below the non-financial business economy average (138.8%). The gross operating rate was also relatively low, as the gross operating surplus was equivalent to 6.3% of the sector's turnover, around two thirds of the rate recorded for the whole of the non-financial business economy (9.7%).

Sectoral analysis

General-purpose machinery is machinery that is typically used in a wide range of different activities — a separation is made between machinery that is power related (Group28.1), on one hand, and other general purpose equipment (Group28.2) on the other hand. These two general-purpose machinery manufacturing subsectors were the largest subsectors in the EU-27's machinery and equipment manufacturing sector in 2009, each with around one third of the sector's value added and a similar, but slightly smaller share of the sector's workforce.

Special-purpose machinery is machinery designed for exclusive use in one or a small cluster of activities. The manufacture of metal forming machinery and machine tools (Group28.4) was somewhat larger than the manufacture of agricultural and forestry machinery (Group28.3), but neither of these subsectors recorded a share of EU-27 sectoral employment or value added in excess of 10% in 2009. As such, the third largest subsector was the manufacture of other special-purpose machinery (Group28.9) which contributed just under one quarter of sectoral value added and employed just over one quarter of the sectoral workforce.

The two general-purpose machinery manufacturing subsectors recorded the highest levels of apparent labour productivity in 2009, EUR 60 thousand per person employed for the EU-27's power related machinery manufacturing subsector and EUR 52 thousand per person employed for other general-purpose machinery. The manufacture of other special-purpose machinery was the only other subsector to register apparent labour productivity above the manufacturing average in 2009, although apparent labour productivity ratios for the two smallest subsectors were above the non-financial business economy average.

The power related general-purpose machinery manufacturing subsector also had the highest average personnel costs within the EU-27's machinery and equipment manufacturing sector in 2009, at EUR 45 thousand per employee. The lowest average personnel costs were EUR 34.7 thousand per employee for the manufacture of agricultural and forestry machinery which remained above the manufacturing average (EUR 30.0 thousand per employee).

These relatively high average personnel costs brought down the wage-adjusted labour productivity ratios for most of the EU-27's machinery and equipment manufacturing subsectors. This ratio ranged in 2009 from 106.7% for the manufacture of metal forming machinery and machine tools to 132.4% for the power related general-purpose machinery manufacturing subsector; the latter was the only one of the five subsectors to record a ratio above the manufacturing average (132.1%).

Turning to operating profitability, both of the EU-27's general-purpose machinery subsectors recorded gross operating rates above the manufacturing average (7.0%) in 2009, while the three special-purpose machinery manufacturing subsectors had gross operating rates that were below this level. The lowest rate was recorded for the manufacture of metal forming machinery and machine tools, as the EU-27's gross operating surplus was just 2.6% of turnover in 2009, the fourth lowest gross operating rate among the manufacturing NACE divisions in 2009.

Country analysis

The highest level of value added in the machinery and equipment manufacturing sector was generated in Germany, EUR 59825 million, equivalent to 39.9% of the EU-27 total in 2009. Germany was the largest Member State in value added terms in each of the five machinery and equipment manufacturing subsectors; its share of EU-27 value added peaked at 53.2% for the manufacture of metal forming machinery and machine tools.

The relative importance of the machinery and equipment manufacturing sector was highest in Hungary and Germany where its share of non-financial business economy value added was 5.0% and 4.9% respectively. The next most specialised Member States in this sector were Denmark (4.4% of non-financial business economy value added), Finland (4.2%) and Italy (4.0%), while the least specialised Member States were Estonia, Portugal, Lithuania, Latvia and Cyprus – as less than 1% of their non-financial business economy value added was generated in this sector in 2009.

Hungary's high specialisation was due, in large part, to its high degree of specialisation in the power related general-purpose machinery manufacturing subsector and, to a lesser extent, its specialisation in the agricultural and forestry machinery manufacturing subsector; Hungary was relatively unspecialised in the remaining subsectors. In contrast, Germany was relatively specialised across all five subsectors that make-up the machinery and equipment manufacturing sector, as the share of non-financial business economy value added that was generated by these five subsectors was consistently higher in Germany than in the EU-27 as a whole; Germany's highest degree of specialisation (within the machinery and equipment manufacturing sector) was recorded for the manufacture of metal forming machinery and machine tools subsector.

The wage-adjusted labour productivity ratio for the machinery and equipment manufacturing sector in 2009 was less than 120% in Germany and Estonia and fell below 100% in Sweden. Indeed, the wage-adjusted labour

productivity ratio for the machinery and equipment manufacturing sector was below the non-financial business economy average in most Member States, with the most notable exception being Hungary where a ratio of 302.7% was recorded, far above the 160.1% average for the whole of the Hungarian non-financial business economy. Italy, Poland, Spain and Cyprus also recorded wage-adjusted labour productivity ratios for the machinery and equipment manufacturing sector that were above their national non-financial business economy averages, but to a much smaller extent.

Ireland had the highest gross operating rate (19.8%) in the machinery and equipment manufacturing sector in 2009 and was one of only three Member States – the others were Hungary and Poland – where the gross operating rate for this sector was above the national non-financial business economy average. Luxembourg had a negative gross operating rate for its machinery and equipment manufacturing sector in 2009, indicating that value added was less than personnel costs (resulting in a negative gross operating surplus).

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the machinery and equipment manufacturing sector in the EU, as covered by NACE Rev.2 Division28. This division includes the manufacture of machinery and equipment that act independently on materials either mechanically or thermally or perform operations on materials (such as handling, spraying, weighing or packing), including their mechanical components that produce and apply force, and any specially manufactured primary parts. This includes the manufacture of fixed and mobile or hand-held devices, regardless of whether they are designed for industrial, building and civil engineering, agricultural or home use. The manufacture of special equipment for passenger or freight transport within demarcated premises also belongs within this division.

This division distinguishes between the manufacture of special-purpose machinery and general-purpose machinery. General-purpose machinery is machinery that is typically used in a wide range of different activities – a separation is made between machinery that is power related (engines and turbines, pumps and compressors, taps and valves, bearings, gears, gearing and driving elements), on one hand, and other general purpose equipment (ovens, furnaces and furnace burners, lifting and handling, non-computer office equipment, power-driven hand tools and non-domestic cooling and ventilation equipment) on the other hand. Special-purpose machinery is machinery designed for exclusive use in one or a small cluster of activities – a separation is made between activities in agriculture and forestry, on one hand, and industrial activities on the other hand. This division also includes other special purpose machinery, not covered elsewhere in the classification, whether or not used in a manufacturing or industrial process, such as fairground amusement equipment, automatic bowling alley equipment, and so on.

This NACE division is composed of five groups:

- the manufacture of general-purpose machinery (Group28.1);
- the manufacture of other general-purpose machinery (Group28.2);
- the manufacture of agricultural and forestry machinery (Group28.3);
- the manufacture of metal forming machinery and machine tools (Group28.4);
- the manufacture of other special-purpose machinery (Group28.9).

This division excludes the manufacture of metal products for general use (which are included as part of the [manufacture of fabricated metal products](#) , Division25). It also excludes associated control devices, computer

equipment, measurement and testing equipment, electricity distribution and control apparatus (as covered by the [manufacture of computer, electronic and optical products](#) and the [manufacture of electrical equipment](#) , Divisions26 and 27), as well as general-purpose motor vehicles (as covered by the [manufacture of motor vehicles, trailers and semi-trailers](#) and the [manufacture of other transport equipment](#) , Divisions29 and 30).

Table 4b: Key indicators, manufacture of motor vehicles, trailers and semi-trailers (NACE Division29), 2009 - Source: Eurostat (sbs_na_ind_r2)

Main statistical findings

Structural profile

The motor vehicles, trailers and semi-trailers manufacturing sector (Division29) in the EU-27 comprised 20 thousand enterprises in 2009, just 0.1% of the total for the whole of the non-financial business economy (Sections B to J and L to N and Division95). There were 2.2 million persons employed in the EU-27's motor vehicles, trailers and semi-trailers manufacturing sector and together they generated EUR99000 million of value added in 2009 – these figures represented 1.7% of the non-financial business economy workforce and 1.8% of total value added in the non-financial business economy. In employment and value added terms, the motor vehicles, trailers and semi-trailers manufacturing sector was the fourth largest NACE division within manufacturing (Section C) in the EU-27, contributing 7.1% of manufacturing value added and 7.2% of employment in 2009.

In 2009, the EU-27's motor vehicles, trailers and semi-trailers manufacturing sector was one of only two manufacturing NACE divisions (the other was the repair and installation of machinery and equipment, Division33) to record apparent labour productivity below the manufacturing average accompanied by average personnel costs above the manufacturing average. Apparent labour productivity in the EU-27's motor vehicles, trailers and semi-trailers manufacturing sector was EUR45 thousand per person employed, slightly below the manufacturing average (EUR46 thousand) but above the non-financial business economy average (EUR41.6 thousand). Average personnel costs were particularly high at EUR41.8 thousand per employee in motor vehicles, trailers and semi-trailers manufacturing compared with an average of EUR30.0 thousand per employee for the whole of the non-financial business economy and EUR34.5 thousand per employee for manufacturing.

The combination of high average personnel costs and apparent labour productivity close to the manufacturing average in 2009 resulted in a particularly low wage-adjusted labour productivity ratio, some 106.9% for the EU-27's motor vehicles, trailers and semi-trailers manufacturing sector. This was the second lowest ratio among the manufacturing NACE divisions in 2009, higher only than that recorded for the repair and installation of machinery and equipment sector (104.2%) and the seventh lowest wage-adjusted labour productivity ratio among all non-financial business economy NACE divisions.

Equally, the gross operating rate (the relation between the gross operating surplus and turnover) for the motor vehicles, trailers and semi-trailers manufacturing sector was also very low. The gross operating rate is a measure of operating profitability, and stood at 1.2% for the EU-27's motor vehicles, trailers and semi-trailers manufacturing sector in 2009, the lowest rate among manufacturing NACE divisions and the third lowest rate among all NACE divisions within the non-financial business economy.

Sectoral analysis

The EU-27's motor vehicles, trailers and semi-trailers manufacturing sector is dominated by two large subsectors, namely motor vehicle manufacturing (Group29.1) and motor vehicle parts and accessories manufacturing (Group29.3), which together contributed more than nine tenths of the sector's employment and value added in 2009. The third subsector, the manufacture of motor vehicle bodies, trailers and semi-trailers (Group29.2) employed 7.7% of the sector's workforce and contributed 6.4% of its value added.

As can be seen from Figure 1, the contribution of the two largest subsectors to the EU-27's motor vehicles, trailers and semi-trailers manufacturing total varied greatly depending on the indicator used for analysis; this diversity impacted on the derived indicators concerning productivity, as shown in Table 2b. The high share of sectoral value added in the motor vehicles manufacturing subsector was reflected in apparent labour productivity that, at EUR55 thousand of value added per person employed, was well above the manufacturing average (EUR46 thousand). The two other subsectors recorded apparent labour productivity ratios not only below the manufacturing average but also below the non-financial business economy average (EUR41.6 thousand per person employed). A slightly different situation could be observed for average personnel costs: again the motor vehicles manufacturing subsector recorded the highest level, but the two other subsectors also recorded average personnel costs that were above the non-financial business economy average.

Despite the relatively high apparent labour productivity recorded for the EU-27's motor vehicles manufacturing subsector the extremely high average personnel costs in this subsector resulted in a wage-adjusted labour productivity ratio of 101.4% – in other words, apparent labour productivity per person employed was just 1.4% higher than average personnel costs per employee. As such, this sector recorded the second lowest wage-adjusted labour productivity ratio within the EU-27 for manufacturing NACE groups in 2009, and the tenth lowest among the 182 non-financial business economy NACE groups for which data are available. While the motor vehicles manufacturing subsector had the lowest wage-adjusted labour productivity ratio within the EU-27's motor vehicles, trailers and semi-trailers manufacturing sector, neither of the two other subsectors achieved a wage-adjusted labour productivity ratio that surpassed the manufacturing or non-financial business economy averages. The wage-adjusted labour productivity ratio for vehicle parts and accessories manufacturing was 116.7% in 2009. For the manufacture of motor vehicle bodies, trailers and semi-trailers the wage-adjusted labour productivity ratio was 135.0% in 2008, which can be compared with the 2008 manufacturing average of 145.3%; although a precise value is not available, the wage-adjusted labour productivity ratio for this subsector in 2009 was around 20 percentage points below the manufacturing average (132.1%).

The EU-27's vehicle parts and accessories manufacturing subsector and the manufacture of motor vehicle bodies, trailers and semi-trailers subsector recorded gross operating rates of 3.5% and 3.2% respectively in 2009. These rates were around half the average gross operating rate recorded across the whole of manufacturing (7.0%), but well above the motor vehicles, trailers and semi-trailers manufacturing sector's average of 1.2%. For the motor vehicles manufacturing subsector, the EU-27 gross operating rate in 2008 was 3.6% compared with a manufacturing average of 8.3%; for this subsector a precise gross operating rate in 2009 is not available but it is likely that this was close to zero as the gross operating surplus was very small as personnel costs accounted for 98.1% of value added.

Country analysis

The German share of EU-27 value added recorded in the motor vehicles, trailers and semi-trailers manufacturing sector was the highest share for Germany in any of the non-financial business economy NACE divisions (with data available) in 2009: German value added was EUR46639 million, equivalent to 44.1% of the EU-27 total. Within the motor vehicles manufacturing subsector German value added was more than half (51.1%) of the EU-27 total. In the two remaining subsectors, Germany also had the highest share of value added, with more than one quarter (26.6%) of the EU-27 total for the manufacture of motor vehicle bodies, trailers and semi-trailers and more than one third (35.8%) of the EU-27 total for vehicle parts and accessories manufacturing.

In relative terms, the Member States most specialised in the motor vehicles, trailers and semi-trailers manufacturing sector were the Czech Republic and Slovakia, as this sector contributed 5.2% of non-financial business economy value added, closely followed by Hungary (5.0%). Further behind this group of central European Member States was Germany where the next highest specialisation ratio was recorded (as the motor vehicles,

trailers and semi-trailers manufacturing sector contributed 3.5% of German non-financial business economy value added), followed by Romania (2.8%), Poland (2.5%) and Slovenia (2.4%). In all the remaining Member States (no data available for Greece, Luxembourg or Malta), the contribution of the motor vehicles, trailers and semi-trailers manufacturing sector to non-financial business economy value added was less than the 1.8% average for the EU-27; the least specialised Member States in 2009 were Cyprus, Latvia, Lithuania and Ireland where the motor vehicles, trailers and semi-trailers manufacturing sector's share of non-financial business economy value added was 0.2% or less.

The low wage-adjusted labour productivity ratio recorded for the EU-27 as a whole in the motor vehicles, trailers and semi-trailers manufacturing sector reflected the very low ratios recorded in several Member States. Germany, the largest Member State in this sector in the EU-27, recorded a wage-adjusted labour productivity ratio below 100% in 2009, indicating that average personnel costs per employee were higher than value added per person employed; this situation was also observed in Lithuania and Sweden. In contrast, Poland and Hungary recorded wage-adjusted labour productivity ratios in excess of 200%; these were well above their national non-financial business economy averages. Wage-adjusted labour productivity ratios above national non-financial business economy averages were also recorded for the motor vehicles, trailers and semi-trailers manufacturing sector in the Czech Republic, Slovenia, Austria, Italy, the Netherlands and Slovakia.

The same Member States that reported wage-adjusted labour productivity ratios below 100% in the motor vehicles, trailers and semi-trailers manufacturing sector also reported negative gross operating rates in 2009, ranging from -1.1% in Germany to -5.7% in Sweden. Hungary and Cyprus were the only Member States to report a gross operating rate for the motor vehicles, trailers and semi-trailers manufacturing sector that was above their national non-financial business economy average.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the motor vehicles, trailers and semi-trailers manufacturing sector in the EU, as covered by NACE Rev.2 Division29. This division includes the manufacture of motor vehicles for transporting passengers or freight, the manufacture of trailers and semi-trailers, and the manufacture of various parts and accessories.

Motor vehicles include passenger cars, commercial vehicles (vans, lorries and over-the-road tractors for semi-trailers), coaches, buses, trolley-buses, snowmobiles, golf carts, amphibious vehicles, fire engines, street sweepers, travelling libraries, armoured cars, concrete-mixer lorries, ATVs, go-carts and race cars. Also included are motor vehicle engines (other than electric ones) and chassis.

This NACE division is composed of three groups:

- the manufacture of motor vehicles (Group29.1);
- the manufacture of bodies (coachwork) for motor vehicles; manufacture of trailers and semitrailers (Group29.2);
- the manufacture of motor vehicle parts and accessories (Group29.3).

Excluded from the statistics that are presented in this article are specialist agricultural or industrial machinery (such as agricultural tractors or off-road dumping trucks) which are classified to [machinery and equipment](#) (Division28) and tanks and other military fighting vehicles (Division30, [manufacture of other transport equipment](#)). The maintenance and repair of vehicles produced in this activity are classified to [motor trades](#) (Division45).

Main statistical findings

Structural profile

The EU-27's non-metallic mineral products manufacturing sector (Division 23) was composed of 99.7 thousand enterprises in 2009. Employment in this sector reached 1.4 million persons which was 1.0% of all the persons employed in the non-financial business economy (Sections B to J and L to N and Division 95) and 4.6% of the total number of persons employed in manufacturing (Section C). The sector generated EUR 63 000 million of value added which was equivalent to 1.1% of the non-financial business economy total and 4.5% of the manufacturing total – similar shares to those observed for employment.

The **apparent labour productivity** of the EU-27's non-metallic mineral products manufacturing sector in 2009 was EUR45 thousand per person employed, above the non-financial business economy average of EUR41.6 thousand per person employed but slightly below the manufacturing average of EUR46 thousand per person employed. **Average personnel costs** within the EU-27's non-metallic mineral products manufacturing sector (EUR32.5 thousand per employee) were also midway between the averages for the non-financial business economy (EUR30.0 thousand per employee) and manufacturing (EUR34.5 thousand per employee). Consequently, the 138.1% recorded for this sector's **wage-adjusted labour productivity ratio** (which combines the two previous indicators and shows the extent to which value added per person employed covers average personnel costs per employee) was very close to the non-financial business economy average (138.8%) and just 6 percentage points above the manufacturing average (132.1%).

The EU-27's non-metallic mineral products manufacturing sector recorded a **gross operating rate** of 9.6% in 2009. Although this was only 2.6 percentage points above the manufacturing average (7.0%) and did not quite reach the non-financial business economy average (9.7%), it was the fourth highest gross operating rate among the manufacturing NACE divisions in 2009.

Sectoral analysis

The eight subsectors that make-up the non-metallic mineral products manufacturing sector are shown in Figure 1 in terms of their employment and value added contributions to the sectoral total for the EU-27 in 2009. The two largest subsectors – using these measures – were the manufacture of articles of concrete, cement and plaster (Group23.6) and glass and glass products manufacturing (Group23.1). The cutting, shaping and finishing of stone subsector (Group23.7, hereafter referred to as the working of stone subsector) had the third largest workforce, but its value added was smaller than that recorded for cement, lime and plaster manufacturing (Group23.5), clay building materials manufacturing (Group23.3) and also the manufacture of abrasive products and non-metallic mineral products not elsewhere classified (Group23.9). The next smallest subsector in value added terms was the manufacture of other porcelain and ceramic products (Group23.4), while the manufacture of refractory products (Group23.2) had the lowest value added and employment of all subsectors.

The various subsectors within the EU-27's non-metallic mineral products manufacturing sector displayed very varied characteristics in terms of their productivity and operating profitability, as can be seen in Table 2b. Value added per person employed in 2009 ranged from EUR28.0 thousand for the manufacture other porcelain and ceramic products and EUR30 thousand for the working of stone to EUR116 thousand for cement, lime and plaster manufacturing, a range of four to one. Apart from cement, lime and plaster manufacturing, the only subsector to record apparent labour productivity above the sectoral and manufacturing averages was the manufacture of abrasive products and non-metallic mineral products not elsewhere classified.

In contrast, average personnel costs were above the manufacturing average (EUR30.0 thousand per employee) for most subsectors within the EU-27's non-metallic mineral products manufacturing sector. The manufacture of other porcelain and ceramic products recorded the lowest average personnel costs (EUR24.4 thousand per employee) in 2009 and was one of only two subsectors – the other was the working of stone – to record average personnel costs below the manufacturing average. Again, the cement, lime and plaster manufacturing subsector recorded the highest level for this ratio, with average personnel costs of EUR48.8 thousand per employee.

The wage-adjusted labour productivity ratios within the EU-27's non-metallic mineral products manufacturing sector were generally quite low, with the sectoral average (138.1%) boosted by the 237.2% ratio for the cement, lime and plaster manufacturing subsector: this was the third highest among all manufacturing NACE groups in 2009. The only other subsectors with a ratio above the manufacturing average (132.1%) were the manufacture of abrasive products and non-metallic mineral products not elsewhere classified and the manufacture of articles of concrete, cement and plaster. Three subsectors recorded wage-adjusted labour productivity ratios below 120%, namely refractory products manufacturing, the manufacture of other porcelain and ceramic products and the working of stone.

A ranking of the subsectors based on the gross operating rate had some similarities to that for the wage-adjusted labour productivity ratio, namely that the highest and lowest rates were again recorded for the cement, lime and plaster manufacturing subsector (22.5%) and the manufacture of refractory products subsector (3.6%); the rate for cement, lime and plaster manufacturing subsector was the second highest among all manufacturing NACE groups. Unlike the ranking based on the wage-adjusted labour productivity ratio, the working of stone recorded the second highest gross operating rate, 9.8%, which was just above the non-financial business economy average.

More generally, most subsectors (the exception being the manufacture of refractory products) recorded gross operating rates above the manufacturing average.

Country analysis

The largest Member States in the EU-27's non-metallic mineral products manufacturing sector in 2009 were Germany and Italy, with 19.9% and 16.0% shares of EU-27 value added respectively. The same two Member States had the largest workforces in this sector, but with their positions reversed: Italy employed 16.6% of the EU-27's workforce in this sector while Germany's share was 15.9%. As Table 3 shows, either Germany or Italy were the largest Member State (in value added terms) for seven of the eight subsectors for which data are available, the one exception being cement, lime and plaster manufacturing where Spain was the largest producer.

The relative importance of the non-metallic mineral products manufacturing sector in value added terms in 2009 was highest in Bulgaria where it contributed 2.2% of the non-financial business economy total, double the average share for the EU-27. Also relatively specialised in this sector were Poland, Cyprus, Romania, the Czech Republic and Portugal, where the non-metallic mineral products manufacturing sector contributed 2.1% of non-financial business economy value added. The least specialised Member States in this sector were the United Kingdom (0.5% of non-financial business economy value added) and Ireland (0.6%); Norway was also relatively unspecialised (0.6%). Looking at the relative importance of employment in this sector, Slovakia and the Czech Republic were the most specialised, each with 1.7% of their non-financial business economy workforce engaged within the non-metallic mineral products manufacturing sector.

The position of Bulgaria as the most specialised Member State in this sector in 2009 resulted from a relatively high specialisation in several subsectors, although Bulgaria was not the most specialised Member State for any individual subsector. This situation can be contrasted with that of Cyprus, which was the third most specialised Member State in the non-metallic mineral products manufacturing sector due to its particularly high specialisation for the manufacture of articles of concrete, cement and plaster, as well as for the manufacture of cement, lime and plaster (where it was the fifth most specialised) and to a lesser extent the smaller working of stone subsector.

Among the Member States, Romania, Bulgaria and Poland recorded the highest wage-adjusted labour productivity ratios in the non-metallic mineral products manufacturing sector in 2009; all three recorded ratios in excess of 200% that were also well above their national non-financial business economy averages. The same three Member States recorded high gross operating rates, again well above national non-financial business economy averages, as did Greece.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the non-metallic mineral products manufacturing sector in the EU, as covered by NACE Rev.2 Division23. This division includes manufacturing activities related to a single substance of mineral origin, for example, mined or quarried sand, gravel, stone or clay. This division also includes the manufacture of glass and glass products (for example, flat glass, hollow glass, glass fibres, technical glassware, glass insulators and so on), tiles and baked clay products, ceramic products (including tableware, sanitary fixtures, insulators and technical products), and cement and plaster, from raw materials to finished articles. The manufacture of shaped and finished stone and other mineral products is also included in this division.

This NACE division is composed of eight groups:

- the manufacture of glass and glass products (Group23.1);
- the manufacture of refractory products (Group23.2);
- the manufacture of clay building materials (Group23.3);
- the manufacture of other porcelain and ceramic products (Group23.4);
- the manufacture of cement, lime and plaster (Group23.5);
- the manufacture of articles of concrete, cement and plaster (Group23.6);
- the cutting, shaping and finishing of stone (Group23.7);
- the manufacture of other non-metallic mineral products (Group23.9).

Main statistical findings

Structural profile

There were 14 thousand enterprises operating with other transport equipment manufacturing (Division30) as their main activity in the EU-27 in 2009. These enterprises employed 747 thousand persons, equivalent to 0.6% of all persons employed in the non-financial business economy (SectionsB to J and L to N and Division95) and 2.4% of the manufacturing (SectionC) workforce. The other transport equipment manufacturing sector generated EUR43239 million of value added which was 0.8% of the non-financial business economy total and 3.1% of the manufacturing total.

The apparent labour productivity of the EU-27's other transport equipment manufacturing sector in 2009 was EUR58 thousand per person employed, around 40% above the non-financial business economy average of EUR41.6 thousand per person employed and 26% above the manufacturing average (EUR46 thousand per person employed). Average personnel costs within the EU-27's other transport equipment manufacturing sector were also high, EUR46.3 thousand per employee compared with an average of EUR30.0 thousand per employee for the whole of the non-financial business economy and EUR34.5 thousand per employee for manufacturing.

The wage-adjusted labour productivity ratio was 125.1% within the other transport equipment manufacturing sector in 2009 showing that apparent labour productivity was one quarter (25.1%) above average personnel costs. Although well below the non-financial business economy average (138.8%) and the manufacturing average (132.1%), this wage-adjusted labour productivity ratio for other transport equipment manufacturing was far higher than that recorded for motor vehicles, trailers and semi-trailers manufacturing (106.9%). Equally, the gross operating rate, which is a measure of operating profitability showing the relation between the gross operating surplus and turnover, was relatively low for the other transport equipment manufacturing sector (5.8%), but higher than for motor vehicles, trailers and semi-trailers manufacturing (1.2%).

Sectoral analysis

The manufacture of air and spacecraft and related machinery (Group30.3) was the largest subsector within the EU-27's other transport equipment manufacturing sector in 2009, accounting for three fifths (60.0%) of sectoral value added and nearly half (47.5%) of sectoral employment. The building of ships and boats (Group30.1) was substantially larger than the manufacture of railway locomotives and rolling stock (Group30.2) in terms of employment, but less so in value added terms – see Figure 1. The miscellaneous activity of the manufacture of

transport equipment not elsewhere classified (Group30.9) was the fourth largest subsector, while the manufacture of military fighting vehicles (Group30.4) was the smallest.

EU-27 apparent labour productivity recorded for these five subsectors ranged in 2009 from less than EUR40 thousand per person employed for the building of ships and boats subsector and the manufacture of transport equipment not elsewhere classified subsector to more than EUR70 thousand per person employed for the manufacture of air and spacecraft and related machinery as well as military fighting vehicles subsectors. There was a similar distribution of average personnel costs: the only subsector in the EU-27 with average personnel costs below the manufacturing average in 2009 was the manufacture of transport equipment not elsewhere classified (EUR31.4 thousand per employee), while the manufacture of military fighting vehicles recorded average personnel costs of EUR59.4 thousand per employee which was almost double the non-financial business economy average (EUR30.0 thousand).

These high average personnel costs pulled down the wage-adjusted labour productivity ratio for most subsectors. Among the five subsectors within the other transport equipment manufacturing sector, the manufacture of railway locomotives and rolling stock recorded the highest wage-adjusted labour productivity ratio in the EU-27, 139.4%, and this was the only subsector where this ratio surpassed the manufacturing average (132.1%) in 2009. By far the lowest wage-adjusted labour productivity ratio was recorded for the building of ships and boats subsector, 106.7%, around 25 percentage points below the manufacturing average.

Equally, for the gross operating rate, the only subsector to record a rate above the manufacturing average in the EU-27 in 2009 was the manufacture of railway locomotives and rolling stock, its 8.3% gross operating rate situated between the manufacturing and non-financial business economy averages. The building of ships and boats subsector recorded the lowest gross operating rate among these five subsectors that constitute the other transport equipment manufacturing sector, at just 2.0% in 2009.

Country analysis

The other transport equipment manufacturing sector was one of only two manufacturing NACE divisions where France had the largest share of EU-27 value added in 2009 – the other was [beverages manufacturing](#) (Division11). France contributed 24.4% of the EU-27's value added in the other transport equipment manufacturing sector, with this share rising to 30.7% for the manufacture of air and spacecraft and related machinery and 39.3% for the manufacture of military fighting vehicles. Among the three other subsectors, Italy's 37.1% share of EU-27 value added for the manufacture of transport equipment not elsewhere classified was the highest share recorded by any Member State. Across the whole of the other transport equipment manufacturing sector, the United Kingdom had the second largest share of EU-27 value added in 2009, around one fifth (20.7%) of the total, while Germany was the third largest with a slightly smaller share (18.8%). The United Kingdom had the largest workforce in the other transport equipment manufacturing sector, 155.1 thousand persons compared with 125.5 thousand in France (employees rather than persons employed) and 113.6 thousand in Germany.

France not only accounted for the highest share of EU-27 value added in the other transport equipment manufacturing sector, but also had the largest share in relative terms: as other transport equipment manufacturing generated 1.3% of non-financial business economy value added in France. Other Member States where the other transport equipment manufacturing sector recorded a relatively high share of non-financial business economy value added in 2009 included the United Kingdom, Romania and Italy; Norway and Croatia were also relatively specialised. The least specialised Member States in the other transport equipment manufacturing sector in 2009 (in value added terms) were Ireland, Portugal, Denmark, Estonia and Cyprus.

Finland and Denmark (2008 data) both recorded a wage-adjusted labour productivity ratio below 100% for the other transport equipment manufacturing sector in 2009, indicating that average personnel costs per employee were higher than the apparent labour productivity per person employed, and these two Member States consequently recorded negative gross operating rates. Hungary, Poland and Slovakia were the only Member States to record wage-adjusted labour productivity ratios and gross operating rates for the other transport equipment manufacturing sector that were above their national non-financial business economy averages in 2009. Poland recorded the highest values for both of these indicators in 2009, with a wage-adjusted labour productivity ratio of 197.0% and a gross operating rate of 20.0%.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the other transport equipment manufacturing sector in the EU, as covered by NACE Rev.2 Division30. This division includes the manufacture of transportation equipment (and parts thereof) such as ships, boats, locomotives, aircraft, military vehicles, motorcycles and bicycles.

The building of ships and boats includes all floating structures for transportation, other commercial purposes, sport and recreational purposes. The manufacture of railway locomotives and rolling stock includes the manufacture of electric, diesel, steam and other rail locomotives, self-propelled railway or tramway coaches, vans and trucks, maintenance or service vehicles and the manufacture of railway or tramway rolling stock that is not self-propelled. Also included are the manufacture of mechanical and electromechanical signalling, safety and traffic control equipment.

The manufacture of air and spacecraft and related machinery includes the manufacture of airplanes for transport, use by the defence forces, sport or other purposes, as well as helicopters, gliders, hang-gliders, dirigibles, hot air balloons, spacecraft, launch vehicles, satellites, orbital stations and intercontinental ballistic missiles. It includes the manufacture of major assemblies such as fuselages, wings, doors, control surfaces, landing gear, as well as motors and engines of a kind typically found on aircraft. The overhaul and conversion of aircraft or aircraft engines is also included.

The manufacture of military fighting vehicles includes the manufacture of tanks, armoured amphibious military vehicles and other military fighting vehicles.

The manufacture of motorcycles includes the manufacture of motorcycles, mopeds and cycles fitted with an auxiliary engine and includes the manufacture of motorcycle engines as well as sidecars and parts and accessories. The manufacture of bicycles and invalid carriages includes the manufacture of non-motorised bicycles and other cycles (such as tricycles), invalid carriages with or without a motor and baby carriages. The manufacture of other transport equipment not elsewhere classified (n.e.c.) includes the manufacture of hand-propelled vehicles (such as luggage trucks, handcarts, sledges and shopping carts) and vehicles drawn by animals.

This NACE division is composed of five groups:

- the building of ships and boats (Group30.1);
- the manufacture of railway locomotives and rolling stock (Group30.2);
- the manufacture of air and spacecraft and related machinery (Group30.3);
- the manufacture of military fighting vehicles (Group30.4);
- the manufacture of transport equipment n.e.c. (Group30.9).

The manufacture of weapons and ammunitions is classified within the [manufacture of fabricated metal products](#) , Division25, while the manufacture of marine and locomotive engines is classified within NACE as part of [machinery and equipment](#) , Division28. Wheeled toys designed to be ridden, including plastic bicycles and tricycles, are classified as toys and their manufacture is included in [other manufacturing](#) , Division32.

Main statistical findings

Structural profile

There were 20 thousand enterprises in the paper and paper products manufacturing (Division17) sector in the EU-27 in 2009 which was around 0.1% of the total for the whole of the non-financial business economy (Sections B to J and L to N and Division95). Employment in the paper and paper products manufacturing sector totalled 658 thousand persons, equivalent to 0.5% of all persons employed in the non-financial business economy and 2.1% of the manufacturing (Section C) workforce. They generated EUR39900 million of value added which was 0.7% of the non-financial business economy total and 2.6% of the manufacturing total.

The wage-adjusted labour productivity ratio in the EU-27's paper and paper products manufacturing sector in 2009 was 146.4%, resulting from apparent labour productivity of EUR56 thousand per person employed, and average personnel costs of EUR38.3 thousand per employee. For all three of these ratios the paper and paper products manufacturing sector recorded a higher value than the manufacturing and non-financial business economy averages.

In contrast, the gross operating rate for the EU-27's paper and paper products manufacturing sector in 2009 was 8.3%, which was situated almost equidistant between the non-financial business economy average (9.7%) and the manufacturing average (7.0%).

Sectoral analysis

The manufacture of articles of paper and paperboard (Group17.2) was the largest subsector within the EU-27's paper and paper products manufacturing sector in 2009 both in terms of employment (71.7%) and value added (61.0%) – see Figure 1. However, the shares of this subsector and the upstream pulp, paper and paperboard manufacturing (Group17.1) subsector were quite different depending on the measure analysed, indicating quite different levels of apparent labour productivity. The pulp, paper and paperboard manufacturing subsector recorded apparent labour productivity per person employed of EUR80 thousand, compared with EUR48 thousand for the manufacture of articles of paper and paperboard subsector. Both of these levels were above the manufacturing average (EUR46 thousand per person employed) and the apparent labour productivity recorded for the pulp, paper and paperboard manufacturing subsector was the eighth highest among all manufacturing NACE groups in 2009.

The high apparent labour productivity figure for the EU-27's pulp, paper and paperboard manufacturing sub-sector was accompanied by high average personnel costs, EUR50.0 thousand per employee in 2009. In contrast, average personnel costs per employee for the manufacture of articles of paper and paperboard were EUR34.0 thousand, which was in line with the manufacturing average of EUR34.5 thousand. The high apparent labour productivity and average personnel costs of the pulp, paper and paperboard manufacturing subsector combined for a wage-adjusted labour productivity ratio of 152.3%, which was itself higher than the ratio for the articles of paper and paperboard manufacturing subsector (140.4%). These wage-adjusted labour productivity ratios for the two paper and paper products manufacturing subsectors were above the manufacturing average (132.1%) and the non-financial business economy average (138.8%).

The two subsectors recorded similar EU-27 gross operating rates in 2009: 8.0% for pulp, paper and paperboard manufacturing and 8.3% for articles of paper and paperboard manufacturing, in both cases these rates were between the manufacturing and non-financial business economy averages (7.0% and 9.7% respectively).

Country analysis

The German share of EU-27 value added within the paper and paper products manufacturing sector in 2009 was 24.7%, broadly in line with its share (27.3%) of EU-27 manufacturing value added as a whole, and much higher than the next highest shares recorded in France (10.8%) and Italy (9.8%). The 8.0% share of EU-27 value added recorded for Sweden in this sector was the highest share for Sweden in any of the non-financial business economy NACE divisions (with data available) in 2009 and the same was true concerning the 5.2% share recorded for Finland. The relative importance of paper and paper products manufacturing was highest in Finland where it accounted for 2.4% of non-financial business economy value added and in Sweden where its share was 2.0%. The least specialised Member States for the paper and paper products manufacturing sector were Ireland and Cyprus, where this sector contributed less than 0.3% of non-financial business economy value added in 2009, a situation that was also observed in Norway.

The high specialisation observed for the two [Nordic Member States](#) of Finland and Sweden was due to a particularly high specialisation in the upstream pulp, paper and paperboard manufacturing subsector, where together these two countries contributed 28.6% of the EU-27's value added and where they were the second and third largest Member States (in value added terms) behind Germany. Concerning the manufacture of articles of paper and paperboard subsector the most specialised Member States were Poland, Hungary, Slovakia and Austria.

In most Member States the paper and paper products manufacturing sector had a higher wage-adjusted labour productivity ratio in 2009 than the non-financial business economy as a whole, with the exceptions of Ireland, Denmark, Cyprus, Finland, Germany and the Netherlands. The Member States where the wage-adjusted labour productivity ratio in this sector was particularly high (relative to the national non-financial business economy average) were Poland, Slovakia, Portugal and Lithuania. While none of the Member States recorded a wage-adjusted labour productivity ratio below 100%, this was the case in Norway where average personnel costs per employee were EUR12 thousand higher than the average value added per person employed.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the paper and paper products manufacturing sector in the EU, as covered by NACE Rev.2 Division17. This division includes the manufacture of pulp, paper and converted paper products. These products form a series of vertically connected processes and more than one activity is often carried out in a continuous process. The manufacture of pulp involves separating the cellulose fibres

from other matter in wood, or dissolving and de-inking used paper, and mixing in small amounts of reagents to reinforce the binding of the fibres. The manufacture of paper involves releasing pulp onto a moving wire mesh so as to form a continuous sheet.

The manufacture of pulp, paper and paperboard includes further processing of paper and paperboard by coating, covering and impregnation, the manufacture of creped or crinkled paper, the manufacture of handmade paper, newsprint and other printing or writing paper.

Converted paper products are made from paper and other materials. The paper articles may be printed (for example, wallpaper, gift wrap and so on), as long as the printing of information is not the main purpose. Included are corrugated paper and paperboard and containers of paper and paperboard, household and sanitary goods, paper stationery, wallpaper and other products, such as labels, filter paper and moulded pulp packaging products (such as egg boxes).

This NACE division is composed of two groups:

- the manufacture of pulp, paper and paperboard (Group17.1);
- the manufacture of articles of paper and paperboard (Group17.2).

Table 4b: Key indicators, manufacture of basic pharmaceutical products and pharmaceutical preparations (NACE Division 21), 2009 - Source: Eurostat (sbs_na_ind_r2)

Main statistical findings

Structural profile

The pharmaceuticals manufacturing (Division 21) sector in the EU-27 is characterised by its small number of very large, capital-intensive enterprises. In total, there were 4.6 thousand enterprises in this sector in 2009. Together they employed 535 thousand persons and generated EUR77198 million of value added.

The large average size of enterprises in this sector can be seen from the share of the pharmaceuticals manufacturing sector within the **non-financial business economy** (Sections B to J and L to N and Division 95): as it represented just 0.02% of all non-financial business economy enterprises, employed 0.4% of the workforce, and generated 1.4% of non-financial business economy value added. Within **manufacturing** (Section C), the pharmaceuticals manufacturing sector contributed 1.7% of the total workforce and 5.5% of total value added.

The **apparent labour productivity** of the EU-27's pharmaceuticals manufacturing sector in 2009 was EUR144 thousand per person employed, nearly 3.5 times as high as the non-financial business economy average of EUR41.6 thousand per person employed and the second highest ratio among the manufacturing NACE divisions in 2009 (behind **tobacco manufacturing**, Division 12). Associated with this high apparent labour productivity ratio were high **average personnel costs**, EUR59.4 thousand per employee for pharmaceutical manufacturing, approximately double the EUR30.0 thousand per employee average for the non-financial business economy and again the second highest level among manufacturing NACE divisions (this time behind the **coke and refined petroleum products manufacturing** subsector, Division 19).

The **wage-adjusted labour productivity ratio** for the EU-27's pharmaceuticals manufacturing sector in 2009 was 242.8%, showing that apparent labour productivity in this sector was approximately 2.4 times as high as average personnel costs. Among manufacturing NACE divisions, this wage-adjusted labour productivity ratio was lower only than that recorded for tobacco manufacturing, while among the NACE divisions within the non-financial business economy this was the seventh highest ratio.

The **gross operating rate** shows the relation between the **gross operating surplus** and **turnover** and this indicates that the pharmaceuticals manufacturing sector had relatively high operating profitability. Its gross operating rate stood at 21.0% for the EU-27's pharmaceuticals manufacturing sector in 2009, more than twice as high as the non-financial business economy average (9.7%) and three times as high as the manufacturing average (7.0%). This was the highest level of profitability (using this measure) among the NACE divisions within manufacturing. It should be noted that this measure does not take account of depreciation or financial

expenditure, which are typically higher in capital-intensive activities.

Sectoral analysis

The EU-27's pharmaceuticals manufacturing sector is split between the large subsector of pharmaceutical preparations manufacturing (Group21.2) and the smaller basic pharmaceutical products manufacturing subsector (Group21.1). In fact, as much as nine tenths of sectoral value added and employment in the EU-27's pharmaceuticals manufacturing sector in 2009 could be attributed to pharmaceutical preparations manufacturing – see Figure 1.

Although varying considerably in size, the two subsectors displayed similar characteristics, namely high levels of labour productivity, average personnel costs and operating profitability. The smaller basic pharmaceutical products manufacturing subsector recorded higher EU-27 apparent labour productivity and lower average personnel costs than the pharmaceutical preparations manufacturing subsector (see Table 2b). As a result, this subsector had a notably higher wage-adjusted labour productivity ratio, 313.9% in 2009, which was the second highest among all manufacturing NACE groups and the tenth highest within the non-financial business economy. The basic pharmaceutical products manufacturing subsector recorded a wage-adjusted labour productivity ratio of 236.2%, which was also well above the manufacturing and non-financial business economy averages and was the fourth highest among all manufacturing NACE groups.

Both subsectors also recorded high gross operating rates within the EU-27 in 2009, 23.5% for the pharmaceutical preparations manufacturing subsector and 20.7% for the basic pharmaceutical products manufacturing subsector; these were the highest and third highest gross operating rates respectively among manufacturing NACE groups in the EU-27.

Country analysis

Just under one fifth of the value added generated in the EU-27's pharmaceuticals manufacturing sector in 2009 was contributed by Germany (19.8%), ahead of Ireland (16.9%), the United Kingdom and France (both 13.3%). The Irish share of EU-27 value added in this sector was the highest contribution made by Ireland to any of the non-financial business economy NACE divisions (with data available) in 2009 and this was also the case for the 0.8% share for Slovenia. The very high ranking of Ireland in this sector reflects its exceptional specialisation: pharmaceuticals manufacturing contributed 15.3% of Irish non-financial business economy value added in 2009. The next most specialised Member State was Slovenia where 3.8% of non-financial business economy value added was generated in pharmaceuticals manufacturing; Switzerland was also very specialised in this sector as 4.7% of non-financial business economy value added was generated in this activity. The least specialised Member State (among those for which data are available), was Estonia where 0.1% of non-financial business economy value added was generated through the manufacture of pharmaceuticals.

Ireland was the most specialised Member State (in value added terms) for both subsectors in 2009. In fact, its specialisation in the basic pharmaceutical products manufacturing subsector was so great that it was the largest Member State in terms of its contribution to EU-27 value added within this subsector, contributing 45.5% of the sectoral total.

Wage-adjusted labour productivity ratios and the gross operating rates for the pharmaceuticals manufacturing sector were generally high, as every Member State for which data are available recorded higher values in this sector for these two indicators than they did, on average, for the whole of manufacturing or the whole of the non-financial business economy. The Irish pharmaceuticals manufacturing sector stood out when analysed in terms of productivity and operating profitability: its gross operating rate was 31.8%, average value added per person employed was EUR788.7 thousand, while its wage-adjusted labour productivity ratio was 1017.3% – the next highest wage-adjusted labour productivity ratio among the Member States was 283.8% in the United Kingdom where the second highest gross operating rate (31.2%) was also recorded. For Ireland, this was the highest wage-adjusted labour productivity ratio across any of the NACE divisions within the non-financial business economy in 2009.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the pharmaceuticals manufacturing sector in the EU, as covered by NACE Rev.2 Division21. The manufacture of basic pharmaceutical products involves the production of medicinal active substances to be used for their pharmacological properties in the manufacture of medicaments, for example, antibiotics, basic vitamins, salicylic and O-acetylsalicylic acids.

Pharmaceutical preparations comprise medicaments (including homeopathic preparations), antisera, blood fractions, vaccines, medical diagnostic preparations and medical impregnated preparations such as wadding, gauze, bandages and dressings.

This NACE division is composed of two groups:

- the manufacture of basic pharmaceutical products (Group21.1);
- the manufacture of pharmaceutical preparations (Group21.2).

Manufacture of rubber and plastic products statistics - NACE Rev. 2

Data from April 2012. Most recent data: Further Eurostat information, Main tables and Database .

This article presents an overview of statistics for the rubber and plastic products manufacturing sector in the European Union (EU) , as covered by NACE Rev.2 Division22.

	Value
Main indicators	
Number of enterprises (1 000)	64
Number of persons employed (1 000)	1 600
Turnover (EUR million)	240 000
Purchases of goods and services (EUR million) (1)	210 000
Personnel costs (EUR million)	50 000
Value added (EUR million)	70 000
Gross operating surplus (EUR million)	20 000
Share in non-financial business economy total (%)	
Number of enterprises	0.3
Number of persons employed (2)	1.2
Value added (2)	1.3
Derived indicators	
Apparent labour productivity (EUR 1 000 per head)	43.0
Average personnel costs (EUR 1 000 per head)	32.0
Wage adjusted labour productivity (%)	138.3
Gross operating rate (%)	8.5

Main statistical findings

Structural profile

There were 64 thousand enterprises classified to rubber and plastic products manufacturing (Division22) in the EU-27 in 2009. Together they employed 1.6 million persons, equivalent to 1.2% of the total number of persons employed in the non-financial business economy (Sections B to J and L to N and Division95) and 5.2% of the manufacturing (Section C) workforce. They generated EUR70000 million of value added which was 1.3% of the non-financial business economy total and 5.0% of the manufacturing total.

The apparent labour productivity of the EU-27's rubber and plastic products manufacturing sector in 2009 was EUR43 thousand per person employed, midway between the non-financial business economy average (EUR41.6 thousand per person employed) and the manufacturing average (EUR46 thousand per person employed). In a similar vein, average personnel costs per employee within this sector – EUR32.0 thousand – were higher than the non-financial business economy average (EUR30.0 thousand) and lower than the manufacturing average (EUR34.5 thousand). The combination of moderate average personnel costs and apparent labour productivity resulted in a wage-adjusted labour productivity ratio for the EU-27's rubber and plastic products manufacturing sector of 138.3% which was almost exactly in line with the non-financial business economy average (138.8%) and slightly above the manufacturing average (132.1%).

The gross operating surplus represented 8.5% of turnover in the EU-27's rubber and plastic products manufacturing sector in 2009. This gross operating rate was slightly lower than the non-financial business economy average of 9.7% and slightly higher than the manufacturing average of 7.0%.

Sectoral analysis

The plastic products manufacturing subsector (Group22.2) was approximately four times the size of the rubber products manufacturing subsector (Group22.1) in the EU-27 – see Figure 1. The fact that the contribution of each subsector to the sectoral total was quite similar in terms of employment and value added underlines the similarity in apparent labour productivity ratios for these two subsectors. For rubber products manufacturing the apparent labour productivity ratio for the EU-27 was slightly higher than for plastics products manufacturing, but both subsectors recorded productivity levels below the manufacturing average while being above the non-financial business economy average. Average personnel costs for rubber products manufacturing were also slightly higher, EUR35.0 thousand per employee, which put this slightly above the manufacturing average. In

contrast, average personnel costs for plastics products manufacturing were EUR30.7 thousand, just above the non-financial business economy average.

The gross operating rate of the EU-27's plastic products manufacturing subsector was, at 8.9%, some two percentage points higher than for rubber products manufacturing. The latter rate was in line with the manufacturing average (7.0%), while for plastic products manufacturing it was closer to the non-financial business economy average (9.7%).

Country analysis

The largest Member State (in value added terms) in the EU-27's rubber and plastic products manufacturing sector in 2009 was Germany, with a 27.7% share of the EU-27 total; furthermore, Germany had the highest value added in both subsectors. Germany's share in EU-27 value added for rubber and plastic products manufacturing was nearly double the next highest share, 14.8% for France; Italy (12.7%) and the United Kingdom (10.6%) were the only other Member States with a share above 10%. In terms of the workforce the three largest Member States in this sector were the same, namely Germany, France (based on employees rather than persons employed) and Italy, while the rubber and plastic products manufacturing workforce in Poland was larger than that in the United Kingdom.

In relative terms, the Czech Republic was by far the most specialised Member State in the rubber and plastic products manufacturing sector, as this sector contributed 3.1% of the value added in the Czech non-financial business economy in 2009. The next most specialised Member States, in value added terms, were Slovenia and Slovakia (both 2.3% of non-financial business economy value added), Poland (2.1%) and Hungary (2.0%). The least specialised Member States, in value added terms, were Latvia, Ireland and Cyprus where this sector contributed 0.5% or less to non-financial business economy value added.

As well as being the most specialised Member State in this sector, the Czech Republic recorded a wage-adjusted labour productivity ratio of 225.1% in 2009, lower only than that recorded in Romania (241.2%); for both of these Member States their wage-adjusted labour productivity ratios for the rubber and plastic products manufacturing sector were substantially above their national averages for the non-financial business economy, as was also the case for Bulgaria, Lithuania, Poland, Portugal and Hungary.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the rubber and plastic products manufacturing sector in the EU, as covered by NACE Rev.2 Division22. This division is characterised by the raw materials used in the manufacturing process, namely rubber and plastics, but not all products made of these materials are classified here.

As well as tyres, rubber manufacturing involves the production of rubber plates, sheets, strip, rods, profile shapes, tubes, pipes, hoses, belts, hygienic articles, parts of footwear, thread, rings, fittings, seals, inflatable mattresses, balloons, brushes, bathing caps, wet suits, diving suits and sex articles as well as rubberised yarn and fabrics.

Plastic manufacturing comprises processing new or spent (in other words, recycled) plastic resins into intermediate or final products, using such processes as: compression moulding; extrusion moulding; injection moulding; blow moulding; and casting.

This NACE division is composed of two groups:

- the rubber products manufacturing subsector (Group22.1);
- the plastic products manufacturing subsector (Group22.2).

Excluded are the manufacture of rubber or plastic footwear (which form part of the [manufacture of leather and related products](#) , Division15), inflatable rubber rafts and boats (which are part of the [manufacture of other transport equipment](#) , Division30) and rubber or plastic sports requisites, games and toys (which form part of [other manufacturing](#) , Division32).

Main statistical findings

Structural profile

The textiles manufacturing (Division13) sector comprised 60 thousand enterprises in the EU-27 in 2009. These enterprises employed 700 thousand persons, equivalent to 0.5% of all persons employed in the non-financial business economy (SectionsB to J and L to N and Division95) and 2.3% of those persons employed in manufacturing (SectionC). The value added generated by the textiles manufacturing sector in 2009 was EUR20000 million, a 0.4% share of the non-financial business economy total and a 1.4% share of the manufacturing total.

In general the textiles manufacturing sector can be characterised by a relatively low apparent labour productivity, in part due to a traditionally high incidence of part-time employment: apparent labour productivity is calculated as the level of value added divided by a simple head count of the number of persons employed, regardless of their working hours. The EU-27's textiles manufacturing sector recorded an apparent labour productivity of EUR29 thousand per person employed in 2009, well below the non-financial business economy average of EUR41.6 thousand per person employed and the manufacturing average of EUR46 thousand per person employed. As such, this sector recorded the fifth lowest apparent labour productivity among the 24 manufacturing NACE divisions in 2009. Average personnel costs within the EU-27's textiles manufacturing sector were below the non-financial business economy average (EUR30.0 thousand per employee) and also below the manufacturing average (EUR34.5 thousand per employee): average personnel costs ranged from EUR22.1 thousand per employee in the preparation and spinning of textile fibres subsector (Group13.1) to EUR26.5 thousand per employee in the weaving of textiles (Group13.2) subsector.

The gross operating rate (the relation between the gross operating surplus and turnover) stood at 6.0% for the EU-27's textiles manufacturing sector in 2009, marginally below the manufacturing average (7.0%) and also below the non-financial business economy average (9.7%).

Sectoral analysis

The vast majority (69.3%) of enterprises within the EU-27's textiles manufacturing sector were active in the miscellaneous subsector concerning the manufacture of other textiles (Group13.9). This subsector was also the largest in employment and value added terms, as its 400 thousand strong workforce accounted for 57.1% of the sectoral total and its EUR12000 million of value added was 60.0% of the sectoral total. From Figure 1 it can be seen that the weaving of textiles (Group13.2) was the next largest subsector, with just under 18% of sectoral employment and value added. Textiles finishing (Group13.3) and the preparation and spinning of textile fibres

(Group13.1) complete the sectoral coverage.

The low apparent labour productivity figure for the whole of the EU-27's textiles manufacturing sector was pulled downwards by the preparation and spinning of textile fibres, as this subsector reported a ratio that was EUR23 thousand per person employed in 2009. The largest subsector, the manufacture of other textiles, recorded the highest apparent labour productivity, EUR30 thousand per person employed, which was nevertheless more than one third below the manufacturing average.

As noted above, average personnel costs within the EU-27's textiles manufacturing sector ranged from EUR22.1 thousand per employee for the preparation and spinning of textile fibres subsector to EUR26.5 thousand per employee for the weaving of textiles subsector. As such, all of the textiles subsectors recorded average personnel costs below the non-financial business economy average (EUR30.0 thousand per employee).

Unlike apparent labour productivity and average personnel costs, the [wage-adjusted labour productivity ratio](#) is less influenced by the incidence of part-time employment. Nevertheless, this ratio was relatively low for all of the textiles manufacturing subsectors. The manufacture of other textiles recorded a wage-adjusted labour productivity ratio of 124.1%, which was by far the highest among the four subsectors, while remaining some way below the non-financial business economy average (138.8%) and the manufacturing average (132.1%). The three remaining subsectors recorded wage-adjusted labour productivity ratios ranging from 102.5% for the preparation and spinning of textile fibres to 107.6% for textiles weaving.

For the gross operating rate, the manufacture of other textiles was the only subsector where this measure of operating profitability exceeded the manufacturing average of 7.0%, although the 8.0% rate that was recorded for this subsector remained below the non-financial business economy average (9.7%). Again, the three smaller subsectors recorded lower values, ranging from a 2.0% gross operating rate for the preparation and spinning of textile fibres to a 4.3% rate for textiles finishing.

Country analysis

Italy was the largest Member State (in value added terms) for the textiles manufacturing sector in 2009, as well as in each of the four subsectors. Italy's share of EU-27 value added averaged 26.8% for the sector as a whole, and ranged from 19.5% for the manufacture of other textiles to 41.6% for the preparation and spinning of textile fibres. The second and third largest Member States in textiles manufacturing were Germany and the United Kingdom, with 15.4% and 10.2% shares of EU-27 value added respectively. In employment terms, Italy's dominance was slightly greater, as 31.0% of the EU-27's textiles manufacturing workforce was in Italy.

The relative importance of the textiles manufacturing sector in value added terms was greatest in Portugal where this sector contributed 1.0% of non-financial business economy value added in 2009. The next most specialised Member States were Italy, where 0.9% of non-financial business economy value added was in textiles manufacturing, followed by Lithuania and Estonia (both 0.8%). The least specialised in this sector, in value added terms, were Ireland, Cyprus and Sweden where the textiles manufacturing sector contributed less than 0.2% of non-financial business economy value added in 2009. The Member States most specialised in the preparation and spinning of textile fibres were Bulgaria, Lithuania, Romania and Italy. For textiles weaving and textiles finishing the two most specialised Member States were Italy and Portugal. For the manufacture of other textiles the most specialised Member States were Estonia, Slovenia, Portugal and Lithuania.

Among the Member States, Romania and Poland recorded the highest wage-adjusted labour productivity ratios within the textiles manufacturing sector in 2009, both in excess of 160%. At the other end of the range, France, Sweden and Italy recorded the lowest ratios, below 110% – see Table 4b.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the textiles manufacturing sector in the EU, as covered by NACE Rev.2 Division13. This division includes the preparation and spinning of textile fibres as well as textile weaving, finishing of textiles, finishing (but not manufacturing of) wearing apparel, the manufacture of made-up textile articles, except apparel (for example, household linen, blankets, rugs, cordage and so on); the [manufacture of wearing apparel](#) is classified to Division14. Textiles may be produced from varying raw materials – for example, silk, wool, other animal, vegetable or man-made fibres, paper or glass.

The preparation and spinning of textile fibres includes the reeling and washing of silk, degreasing and carbonising of wool and dyeing of wool fleece, carding and combing of all kinds of fibres, spinning and manufacture of yarn or thread, twisting, folding, cabling and dipping of filament yarns.

Finishing of textiles includes bleaching, dyeing, dressing, pleating, waterproofing, coating, rubberising, impregnating or silk screen-printing.

The manufacture of other textiles concerns knitted or crocheted fabrics, carpets and rugs, rope, narrow woven fabrics and trimmings and made-up textile articles such as blankets, travelling rugs, bed, table, toilet or kitchen linen, quilts, eiderdowns, cushions, pillows, sleeping bags, made-up furnishing articles (for example, curtains, blinds or bedspreads), tents, sails, sun blinds, dust cloths, dishcloths, life jackets and parachutes.

This NACE division is composed of four groups:

- the preparation and spinning of textile fibres (Group13.1);
- the weaving of textiles (Group13.2), which covers the manufacture of broad woven fabrics;
- the finishing of textiles (Group13.3);
- the manufacture of other textiles (Group13.4).

Excluded are preparatory operations carried out in combination with agriculture (Division01) and the manufacture of synthetic fibres (which forms part of [chemicals manufacturing](#) , Division20).

Table 3b: Key indicators, manufacture of tobacco products (NACE Division12), 2009 - Source: Eurostat (sbs_na_ind_r2)

Main statistical findings

Structural profile

There were 251 enterprises operating with tobacco products manufacturing (Division12) as their main activity in the EU-27 in 2009. This was the second lowest number of enterprises for any of the NACE divisions that constitute the non-financial business economy (Sections B to J and L to N and Division 95) and suggests that the tobacco products manufacturing sector is dominated by a small number of players – these tend to operate internationally. Together they employed 48.5 thousand persons, equivalent to 0.2% of all persons employed in manufacturing (Section C). They generated EUR 8013 million of value added which was 0.6% of the manufacturing total.

Apparent labour productivity of the EU-27's tobacco products manufacturing sector in 2009 was EUR 165 thousand per person employed, around four times as high as the non-financial business economy average of EUR 41.6 thousand per person employed and more than three and a half times as high as the manufacturing average of EUR 46 thousand per person employed. This was the highest apparent labour productivity recorded by any of the manufacturing NACE divisions in the EU-27 in 2009. **Average personnel costs** within the EU-27's tobacco products manufacturing sector were also relatively high, but not to the same extent as apparent labour productivity. Personnel costs per employee averaged EUR 50.0 thousand for tobacco products manufacturing compared with EUR 30.0 thousand for the whole of the non-financial business economy and an average of EUR 34.5 thousand for manufacturing. As such, average personnel costs for tobacco products manufacturing were the third highest among the manufacturing NACE divisions in 2009.

The **wage-adjusted labour productivity ratio** combines the two previous indicators and this was also relatively high due to the elevated apparent labour productivity. The wage-adjusted labour productivity ratio for the EU-27's tobacco products manufacturing sector in 2009 was 329.9%, far above the non-financial business economy average (138.8%) and the manufacturing average (132.1%); the wage-adjusted labour productivity ratio for tobacco products manufacturing in 2009 was by far the highest within manufacturing, and the fourth highest of all NACE divisions within the non-financial business economy.

The ratio of the **gross operating surplus to turnover**) gives an indication of operating profitability, the **gross operating rate** . For the EU-27's tobacco products manufacturing sector in 2009 this rate was 12.5%, considerably higher than both the manufacturing average (7.0%) and the non-financial business economy average (9.7%). Within manufacturing, only the **manufacture of basic pharmaceutical products and pharmaceutical preparations** (Division21) and **other manufacturing** (Division32) had higher gross operating rates in the EU-27 in 2009.

Country analysis

Tobacco manufacturing was highly concentrated within the EU-27 in geographical terms. The Netherlands had the largest tobacco products manufacturing sector among the EU-27 Member States in 2009, accounting for one fifth (20.7%) of the EU-27's value added; this was the highest share for the Netherlands in any of the non-financial business economy NACE divisions (with data available) in 2009. This sector contributed 0.6% of the value added in the Dutch non-financial business economy in 2009, a greater share than in any other Member State. In relative terms, this sector was also important in Bulgaria where it accounted for 0.4% of non-financial business economy value added in 2009.

The Netherlands, Italy and Greece recorded particularly high wage-adjusted labour productivity ratios in the tobacco products manufacturing sector in 2009; for both Italy and Greece this was the highest wage-adjusted labour productivity ratio in any of the NACE divisions within the non-financial business economy in 2009, while for the Netherlands it was the highest among the manufacturing NACE divisions. In general, most of the Member States for which data are available recorded wage-adjusted labour productivity ratios for the tobacco products manufacturing sector that were above their national non-financial business economy averages in 2009, the one exception being Bulgaria. However, this was not the case for the gross operating rate, as Bulgaria, Germany, Hungary and Poland all recorded gross operating rates for tobacco products manufacturing that were below their national non-financial business economy averages.

Data sources and availability

The analysis presented in this article is based on the main dataset for **structural business statistics (SBS)** which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the tobacco products manufacturing sector in the EU, as covered by NACE Rev.2 Division12. This division includes the processing of tobacco into a form suitable for final consumption. It includes the manufacture of tobacco products and products of tobacco substitutes: cigarettes, fine cut tobacco, cigars, pipe tobacco, chewing tobacco, snuff, 'homogenised' or 'reconstituted' tobacco.

This division contains one group and one class only and so there is no analysis of subsectors in this article.

Main statistical findings

Structural profile

There were 128.3 thousand enterprises classified to the wearing apparel manufacturing (Division14) sector in the EU-27 in 2009. Together they employed 1130 thousand persons, equivalent to 0.8% of all persons employed in the **non-financial business economy** (Sections B to J and L to N and Division95) and 3.7% of the **manufacturing** (Section C) workforce. They generated EUR19200 million of value added which was 0.3% of the non-financial business economy total and 1.4% of the manufacturing total.

The **apparent labour productivity** of the EU-27's wearing apparel manufacturing sector in 2009 was EUR17 thousand per person employed: this was the lowest apparent labour productivity ratio recorded among the manufacturing NACE divisions and the second lowest of all divisions within the non-financial business economy in 2009, higher only than for **food and beverage service activities** (Division56). Furthermore, **average personnel costs** within the EU-27's wearing apparel manufacturing sector were also very low, EUR14.2 thousand per employee, which was not only the lowest among all manufacturing NACE divisions, but also the lowest across all of the NACE divisions within the non-financial business economy. For comparison, the non-financial business economy averages for apparent labour productivity and average personnel costs were EUR41.6 thousand per person employed and EUR30.0 thousand per employee respectively, more than double their levels for wearing apparel manufacturing.

The low values of apparent labour productivity and average personnel costs for wearing apparel manufacturing may, in part, be due to a high incidence of part-time work, as both of these indicators are compiled on the basis of a simple head count of persons. In contrast, the **wage-adjusted labour productivity ratio** is calculated as a percentage, showing the relative size of these two ratios to each other, and so reducing substantially the impact of part-time employment. The wage-adjusted labour productivity ratio for the EU-27's wearing apparel manufacturing sector in 2009 was 119.5%. Although this was below both the non-financial business economy average (138.8%) and the manufacturing average (132.1%), the extent to which it was below these two benchmarks was much less than for the earlier mentioned indicators that are calculated on the basis of a head count. The wage-adjusted labour productivity ratio for wearing apparel manufacturing was nevertheless the third lowest across all of the manufacturing NACE divisions.

The **gross operating rate** (the relation between the **gross operating surplus** and **turnover**) for the EU-27's wearing apparel manufacturing sector was 6.4% in 2009, which was below, but relatively close to the manufacturing average of 7.0%.

Sectoral analysis

Nearly nine in every ten enterprises within the EU-27's wearing apparel manufacturing sector were classified to the manufacture of wearing apparel, except fur apparel (Group14.1), with most of the remainder classified to the manufacture of knitted and crocheted apparel (Group14.3); the third subsector within this sector was the manufacture of articles of fur (Group14.2). The manufacture of wearing apparel, except fur apparel also dominated the sector in terms of value added and employment – see Figure 1 – with around 85% of the sectoral total for both of these measures.

The very low apparent labour productivity figure for the whole of the EU-27 wearing apparel manufacturing sector was pulled downwards by the manufacture of wearing apparel, except fur apparel where an average of EUR16 thousand of value added was generated per person employed. This was the lowest apparent labour productivity ratio across all of the manufacturing NACE groups and the third lowest among the 197 NACE groups within the non-financial business economy for which data for 2009 are available. The manufacture of knitted and crocheted apparel recorded somewhat higher apparent labour productivity (EUR21 thousand per person employed), but still well below the manufacturing and non-financial business economy averages; this was the third lowest ratio among the 89 manufacturing NACE groups for which data are available.

A similar situation can be observed for average personnel costs per employee, which ranged from EUR13.8 thousand for the manufacture of wearing apparel, except fur apparel, through EUR16.9 thousand for the manufacture of knitted and crocheted apparel, to EUR20.0 thousand for the manufacture of articles of fur. These values were well below the manufacturing average, and all three subsectors had average personnel costs per employee that were ranked within the bottom six NACE groups across the whole of manufacturing. EU-27 wage-adjusted labour productivity ratios are available for two of the three subsectors for 2009 and these were both close to the sectoral average (119.5%): the ratio for the manufacture of knitted and crocheted apparel (121.9%) was slightly higher than that for the manufacture of wearing apparel, except fur apparel (119.0%). For the gross operating rate these two subsectors also recorded rates either side of the sectoral average, with the smaller subsector of the manufacture of articles of fur recording a rate of 11.0%, which was higher than the manufacturing average (7.0%) and the non-financial business economy average (9.7%).

Country analysis

As for the manufacture of textiles, Italy was the largest Member State (in value added terms) in the EU-27's wearing apparel manufacturing sector in 2009. Italy's share of the EU-27's wearing apparel manufacturing sector was 34.5% in 2009, reaching 40.4% for the manufacture of knitted and crocheted apparel subsector and 33.7% for the manufacture of wearing apparel, except fur apparel subsector. In the smaller subsector of the manufacture of articles of fur Greece had the highest value added, 40.4% of the EU-27 total. Romania generated 4.2% of the EU-27's value added in the wearing apparel manufacturing sector, the highest share for Romania in any of the non-financial business economy NACE divisions (with data available) in 2009, while Bulgaria's 2.0% share in this sector was also its highest share of the EU-27 value added in 2009.

The Italian wearing apparel manufacturing workforce of 224.4 thousand persons was the largest within the EU-27, a 21.6% share of the total; this was followed by Romania (169.2 thousand persons), Poland (127.5 thousand persons) and Bulgaria (117.2 thousand persons). The large differences in the Italian share of the EU-27 total depending upon whether value added or employment is analysed may, in part, reflect the focus of Italian clothes manufacturing on higher value products (including many designer and luxury brands) as opposed to the more labour-intensive stages of clothing production and mass-market products.

In value added terms, the relative importance of the wearing apparel manufacturing sector was highest in Bulgaria, as this sector contributed 2.3% of the Bulgarian non-financial business economy's value added in 2009. The next most specialised Member States were Romania (1.8% of non-financial business economy value added), Portugal (1.3%), Lithuania (1.3%) and Italy (1.1%); Croatia was also specialised in this sector, as wearing apparel manufacturing contributed 1.0% of Croatian non-financial business economy value added.

As already noted, the wage-adjusted labour productivity ratio for wearing apparel manufacturing for the EU-27 was somewhat below the non-financial business economy average in 2009 and this situation was repeated in all Member States for which data are available (see Table 4b). In Italy and Spain the wage-adjusted labour produc-

tivity ratio for wearing apparel manufacturing was closest to national non-financial business economy averages, in both cases within ten percentage points. In four Member States – the Netherlands, Slovakia, Slovenia and Cyprus – ratios below 100% were recorded, indicating that apparent labour productivity per person employed was lower than average personnel costs per employee in this sector in 2009.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the wearing apparel manufacturing sector in the EU, as covered by NACE Rev.2 Division14. This division includes ready-to-wear or made-to-measure tailoring in all materials, for example, leather, fabric, knitted and crocheted fabrics (such as socks, tights, pullovers, cardigans and similar articles). All items of clothing are included (for example, outerwear and underwear), for men, women or children, for all purposes (work, sports or casual clothing) and accessories such as gloves, hats and ties. Also included is the manufacture of articles of fur, including wearing apparel and clothing accessories, rugs and industrial polishing cloths.

This NACE division is composed of three groups:

- the manufacture of wearing apparel (Group14.1);
- the manufacture of articles of fur (Group14.2);
- the manufacture of knitted and crocheted apparel (Group14.3).

Excluded are the dressing and dyeing of fur and the manufacture of footwear (which form part of the [manufacture of leather and related products](#) , Division15), sports and safety headgear as well as fire-resistant and protective safety clothing (which form part of [other manufacturing](#) , Division32).

Table 4b: Key indicators, manufacture of wood and of products of wood and cork, except furniture; manufacture of articles of straw and plaiting materials (NACE Division16), 2009 - Source: Eurostat (sbs_na_ind_r2)

Main statistical findings

Structural profile

The wood and wood products manufacturing (Division16) sector comprised 172 thousand enterprises in the EU-27 in 2009. Together they employed 1.02 million persons, equivalent to 0.8% of the total number of persons employed in the non-financial business economy (Sections B to J and L to N and Division95) and 3.4% of the manufacturing (Section C) workforce. They generated EUR28024 million of value added which was 0.5% of the non-financial business economy total and 2.0% of the manufacturing total.

The apparent labour productivity of the EU-27's wood and wood products manufacturing sector in 2009 was EUR27 thousand per person employed, below the non-financial business economy average of EUR41.6 thousand per person employed and the manufacturing average of EUR46 thousand per person employed. This was one of the lowest levels of apparent labour productivity among the manufacturing NACE divisions, higher only than the manufacture of wearing apparel (Division14) and the manufacture of leather and related products (Division15), and the same level as furniture manufacturing (Division31).

Average personnel costs within the EU-27's wood and wood products manufacturing sector were also relatively low, at EUR22.7 thousand per employee compared with EUR30.0 thousand per employee for the whole of the non-financial business economy and an average of EUR34.5 thousand per employee for manufacturing. Again, this was amongst the lowest ratios within manufacturing (fourth lowest), and was only higher than for the manufacture of wearing apparel, leather and related products, and furniture.

The wage-adjusted labour productivity ratio combines the two previous indicators and shows the extent to which value added per person employed covers average personnel costs per employee. Due to low productivity and only slightly inferior average personnel costs the EU-27's wood and wood products manufacturing sector had a relatively low wage-adjusted labour productivity ratio in 2009, reaching 120.1% – the non-financial business economy average was 138.8% and the manufacturing average was 132.1%.

The gross operating rate (the relation between the gross operating surplus and turnover) is one measure of profitability; it stood at 7.4% for the EU-27's wood and wood products manufacturing sector in 2009, lower than the non-financial business economy average (9.7%) but higher than the manufacturing average (7.0%).

Sectoral analysis

The wood and wood products manufacturing sector includes the first processing stages of sawmilling and planing of wood (Group16.1) and the downstream activity of the manufacture of products of wood, cork, straw and plaiting materials (Group16.2, hereafter referred to as wood products manufacturing). Within the EU-27 the largest of these two activities was wood products manufacturing, which employed just over three quarters (75.7%) of the sectoral workforce in 2009 and generated nearly four fifths (79.0%) of sectoral value added.

Both subsectors recorded relatively low apparent labour productivity and average personnel costs in the EU-27 in 2009, in particular the sawmilling and planing of wood. The apparent labour productivity ratio for the sawmilling and planing of wood was EUR24 thousand per person employed and average personnel costs were EUR18.9 thousand per employee, respectively the fifth and fourth lowest levels for these ratios among the manufacturing NACE groups for which data are available (approximately 90 groups). For wood products manufacturing these ratios were higher, EUR28 thousand value added per person employed and EUR24.0 thousand personnel costs per employee – nevertheless, both of these values were still well below manufacturing averages.

The particularly low average personnel costs for the EU-27's sawmilling and planing of wood subsector helped to lift the wage-adjusted labour productivity ratio for this activity to 124.9% in 2009, ahead of the 118.6% recorded for wood products manufacturing; nevertheless, this ratio remained below the manufacturing average (132.1%) for both subsectors. In contrast, the gross operating rate for these two subsectors was relatively close to the manufacturing average (7.0%), with the 7.9% rate for wood products manufacturing above that recorded for the sawmilling and planing of wood (6.1%).

Country analysis

Germany recorded the highest share (18.1%) of EU-27 value added within the wood and wood products manufacturing sector in 2009, although this share was less than the German share of EU-27 value added for the whole of the non-financial business economy (22.1%) and was also considerably lower than the German share of EU-27 manufacturing (27.3%). Italy (14.7%) and France (10.8%) were the only other Member States with double-digit shares of EU-27 sectoral value added. Nevertheless, the 6.2% share of EU-27 value added recorded for Austria was the highest share for Austria in any of the non-financial business economy NACE divisions (with data available) in 2009; this sector was also where Estonia and Latvia recorded their highest contributions to EU-27 value added in 2009, both 0.8%.

The German value added share was lower for the sawmilling and planing of wood subsector (16.0%) – although it still had the largest value added of any Member State, whereas its share of the EU-27's wood products manufacturing subsector was 18.7%. After Germany, the largest Member States in the sawmilling and planing of wood subsector were France, Sweden and Italy, all with more than 10% of EU-27 value added. For wood products manufacturing, alongside Germany both Italy and France also had shares of EU-27 value added in excess of 10%; among the non-member countries this subsector was also particularly large in Switzerland, where value added was equivalent to more than 10% of the EU-27 total.

With the exception of Sweden, the Member States with the greatest value added in the wood and wood products manufacturing sector were generally not particularly specialised in value added terms. The most specialised Member States in 2009 were the Baltic Member States (in particular, Estonia and Latvia) and Austria, and to a lesser extent Sweden, Finland, the Czech Republic and Romania. The least specialised Member States in the wood and wood products manufacturing sector were Ireland, the United Kingdom, Luxembourg, the Netherlands, France, Hungary and Germany.

Several of the Member States that were relatively specialised in this sector recorded wage-adjusted labour productivity ratios that were well above the EU-27 average, for example, Estonia and Latvia were the most specialised Member States and had ratios of 157.0% and 187.8% respectively, while Romania had a ratio of 224.8% which was the highest of all Member States. Only two Member States had a wage-adjusted labour productivity ratio below 100%, which indicated that average personnel costs per employee were higher than apparent labour productivity per person employed: the relatively specialised Member State of Finland had a ratio of 93.3%, while the least specialised Member State, Ireland, recorded a ratio of just 12.1%.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the wood and wood products manufacturing sector in the EU, as covered by NACE Rev.2 Division16. The production includes processing logs that are cut into bolts, or lumber that may then be cut further, or shaped by lathes or other shaping tools and assembled into finished products.

Classified under the sawmilling and planing of wood are the drying and machining of wood, slicing, peeling or chipping logs, the manufacture of wooden railway sleepers and unassembled wooden flooring, the impregnation or chemical treatment of wood, as well as the manufacture of wood wool, wood flour, chips or particles.

The manufacture of products of wood, cork, straw and plaiting materials includes the production of veneer sheets and wood-based panels, assembled parquet floors, other builders' carpentry and joinery (such as roof frame elements, doors, windows, shutters and their frames, stairs, railings and prefabricated buildings), wooden containers, and other wooden products such as handles, clothes hangers, household utensils and kitchenware, as well as basket-ware and the production of fire logs and pellets.

This NACE division is composed of two groups:

- the sawmilling and planing of wood (Group16.1);
- the manufacture of products of wood, cork, straw and plaiting materials (Group16.2).

This division does not include logging and the production of wood in the rough (which is covered by forestry and logging, part of Division02), the [manufacture of furniture](#) whether fitted or free-standing (Division31), the manufacture of wooden toys, brushes and brooms or coffins (part of [other manufacturing](#) , Division32) or the installation of wooden fittings and the like (part of [specialised construction activities](#) , Division43).

Manufacturing statistics - NACE Rev. 2

Data from April 2012. Most recent data: Further Eurostat information, Main tables and Database

This article presents an overview of statistics for the [European Union's \(EU's\)](#) manufacturing sector, as covered by [NACE Rev.2 Section C](#).

The manufacturing sector includes a vast range of activities and production techniques, from small-scale enterprises using traditional production techniques such as the manufacture of musical instruments to very large enterprises sitting atop a high and broad pyramid of parts and components suppliers collectively manufacturing complex products such as aircraft. An analysis of the manufacturing sector as a whole gives an idea of the scale of this sector, it should be noted however that indicators of its inputs (for example labour or capital goods), its performance, or its size structure are effectively an average across very different activities. While this can also be said of other large and diverse sectors such as construction, distributive trades and transport services, the manufacturing sector is probably the most varied activity within the non-financial business economy at the NACE section level of detail.

	Value
Main indicators	
Number of enterprises (1 000)	2 039
Number of persons employed (1 000)	30 668
Turnover (EUR million)	5 812 027
Purchases of goods and services (EUR million)	4 282 582
Personnel costs (EUR million)	989 022
Value added (EUR million)	1 396 136
Gross operating surplus (EUR million)	407 114
Share in non-financial business economy total (%)	
Number of enterprises	9.8
Number of persons employed (1)	22.9
Value added (1)	25.0

Table 4b: Key indicators, manufacturing (NACE Section C), 2009 - Source: Eurostat (sbs_na_ind_r2)

Main statistical findings

Manufacturing includes the physical or chemical transformation of materials, substances, or components into new products. The raw materials are products of agriculture, forestry, fishing, mining or quarrying as well as products of other manufacturing activities. Substantial alteration, renovation or reconstruction of goods is generally considered to be manufacturing. Selling to the general public products that have been made on the same premises from which they are sold, such as bakeries and custom tailors, is also included in manufacturing rather than retailing.

Manufacturing units may process their own materials, sub-contract a part of the processing of their own materials, own legal rights and concepts of the product but sub-contract the whole processing, or carry out the aforementioned sub-contracted processes. Assembly of the component parts (whether self-produced or purchased) of manufactured products is also considered manufacturing. The output of a manufacturing process may be finished in the sense that it is ready for use or consumption, or it may be semi-finished in the sense that

it is to become an input for further manufacturing.

Specialised installation, maintenance and repair of industrial, commercial and similar machinery and equipment is considered as part of manufacturing, however the [repair of computers and personal and household goods](#) is classified as a service (Division95), while the repair of motor vehicles is classified as part of [distributive trades](#) (SectionG).

Some transformation processes are not classified as manufacturing: logging is classified in forestry (SectionA); materials recovery is considered as primarily [waste processing](#) (SectionE); on-site construction of structures which is classified as part of [construction](#) (SectionF); activities of breaking bulk and redistribution (including, for example, packaging, bottling or sorting) are classified to distributive trades.

Structural profile

Around one in ten (9.8%) of all enterprises in the EU-27's [non-financial business economy](#) (Sections B to J and L to N and Division 95) were classified to manufacturing (SectionC) in 2009, a total of 2.0 million enterprises. The manufacturing sector employed 31 million persons in 2009 and generated EUR1400 billion of [value added](#). By these two measures manufacturing was the second largest of the NACE sections within the EU-27's non-financial business economy in terms of its contribution to employment (22.8%) and the largest contributor to non-financial business economy value added, accounting for one quarter of the total (25.0%).

In 2009 the EU-27's manufacturing sector recorded [apparent labour productivity](#) and [average personnel costs](#) above non-financial business economy averages: the apparent labour productivity of the manufacturing sector was EUR 46 thousand per person employed, some EUR4.4 thousand more than the non-financial business economy average, while average personnel costs in the manufacturing sector were EUR34.5 thousand per employee, EUR4.5 thousand above the non-financial business economy average. Combing these two ratios into the [wage-adjusted labour productivity ratio](#) shows that value added per person employed was equivalent to 132.1% of average personnel costs per employee in manufacturing, which was slightly below the average for the non-financial business economy (138.8%).

The [gross operating rate](#) (the relation between the [gross operating surplus](#) and [turnover](#)) was 7.0% for the EU-27's manufacturing sector in 2009, below the 9.7% average for the non-financial business economy, and as such this sector had the second lowest levels of profitability (using this measure) among any of the NACE sections within the non-financial business economy, with only distributive trades recording a lower gross operating rate (5.1%).

Sectoral analysis

At the NACE division level the manufacturing sector is composed of 24 different subsectors. The largest subsectors in 2009 in terms of EU-27 value added and employment were food manufacturing (Division10), the manufacture of fabricated metal products (Division25) and the manufacture of machinery and equipment (Division28) – see Figure1.

Manufacturing subsectors are very diverse, combining activities with relatively low apparent labour productivity and average personnel costs, such as the manufacture of textiles (Division13), wearing apparel (Division14), leather products (Division15) and furniture (Division31), with other activities that have considerably higher values for the same indicators, such as tobacco manufacturing (Division12), the processing of coke and petroleum (Division19) and the manufacture of basic pharmaceutical products and pharmaceutical preparations (Division21) – see Table2b.

In 2009 apparent labour productivity within the EU-27's manufacturing subsectors ranged from EUR17 thousand per person employed for the manufacture of wearing apparel and EUR23 thousand per person employed for the leather and related products manufacturing subsector to more than EUR100 thousand per person employed for the manufacture of tobacco products, basic pharmaceutical products and pharmaceutical preparations, and coke and refined petroleum products. In line with their very low apparent labour productivity, the manufacture of wearing apparel and of leather and related products recorded the lowest average personnel costs, EUR14.2 thousand per employee and EUR18.2 thousand per employee respectively. Average personnel costs

per employee were EUR66.5 thousand per employee for the manufacture of coke and refined petroleum products, the highest among the manufacturing subsectors and close to double the manufacturing average. The particularly high apparent labour productivity and relatively less elevated average personnel costs resulted in the tobacco manufacturing subsector recording the highest wage adjusted labour productivity ratio (329.9%) among manufacturing subsectors, indicating that value added per person employed was just over three times as high as the average personnel costs per employee in this subsector. The two other subsectors with high apparent labour productivity, namely the manufacture of basic pharmaceutical products and pharmaceutical preparations and coke and refined petroleum products recorded the second and third highest wage-adjusted labour productivity ratios among manufacturing subsectors (242.8% and 170.3%). The repair and installation of machinery and equipment (Division33) recorded the lowest wage adjusted labour productivity ratio (104.2%).

An analysis of the EU-27's gross operating surplus (value added less personnel costs) gives an idea of the operating profit before depreciation charges. The gross operating surplus for the manufacture of basic pharmaceutical products and pharmaceutical preparations was equivalent to 21.0% of the subsector's turnover, substantially above the 14.3% recorded for other manufacturing (Division32) which had the next highest gross operating rate and exactly three times the manufacturing average (7.0%); there was only one other manufacturing subsector (among those for which data are available) with a gross operating rate that was in double figures, namely, the manufacture of tobacco products (12.5%). The remaining subsectors recorded rates between 5.5% for the manufacture of computer, electronic and optical products (Division26) and 9.6% for the manufacture of other non-metallic mineral products (Division23); aside from two very low gross operating rates that were posted for the manufacture of motor vehicles, trailers and semi-trailers (1.2%, Division29) and the manufacture of coke and refined petroleum products (1.6%); these rates were particularly low given the capital-intensive nature of these activities and the related high levels of depreciation.

Country analysis

Because of the tradable (export and import) nature of manufactured goods it follows that the relative importance of manufacturing within the non-financial business economy varies greatly between Member States and also that specialisations at the subsector level are sometimes very pronounced. Figure2 shows that the share of manufacturing within the non-financial business economy's value added varied in 2009 from 7.5% in Luxembourg to 36.2% in Hungary. The range in employment terms was similar, from 13.3% in the Netherlands to 37.5% in Slovakia. The difference between the employment and value added shares was particularly large in Ireland, with the value added share much higher (17.9 percentage points) indicating a particularly high apparent labour productivity in this country, and in turn reflecting a high Irish specialisation in a number of high-technology subsectors.

Among the five largest Member States Germany stands out as it alone contributed more than one quarter (27.3%) of manufacturing value added in the EU-27 in 2009, well above its 22.1% share of value added in the non-financial business economy as a whole. Italy also recorded a larger share of the EU-27's manufacturing value added (12.9%) than it did for the non-financial business economy as a whole (10.6%), while the reverse was true for France, Spain and in particular the United Kingdom.

In value added terms, Germany was the largest Member State in 18 of the 24 subsectors (see Table3) in 2009; Italy was largest in three (the textiles, wearing apparel, and leather and related products manufacturing subsectors); France was the largest Member State for the manufacture of beverages and other transport equipment, while the Netherlands recorded the highest level of added value for the manufacture of tobacco products. Table3 also shows which Member States were the most specialised in each of the subsectors in 2009. The Irish specialisation in the manufacture of basic pharmaceutical products and pharmaceutical preparations was particularly high, as this single subsector accounted for 46.0% of Irish manufacturing value added and for 15.3% of non-financial business economy value added in Ireland; for the EU-27 as a whole this subsector accounted for just 0.4% of non-financial business economy value added. Equally remarkable was the Hungarian specialisation rate for the manufacture of coke and refined petroleum products which accounted for 2.7% of Hungarian non-financial business economy value added compared with an EU-27 average of 0.07%. Other high specialisation ratios were recorded in Bulgaria and Romania for the manufacture of wearing apparel, and in Estonia and Latvia for wood and wood products (Division16); for each of these, the level of activity within the Member States was at least five times as high as the EU-27 average.

Among the Member States the highest apparent labour productivity in manufacturing in 2009 was recorded in Ireland, where it reached EUR162.6 thousand per person employed, reflecting this country's specialisation in

pharmaceutical manufacturing. This was far ahead of the next highest level of apparent labour productivity, namely EUR80.4 thousand per person employed recorded in Belgium. Belgium also recorded the highest average personnel costs within the manufacturing sector in 2009, peaking at EUR54.4 thousand per employee. Average personnel costs were also greater than or equal to EUR50 thousand per employee in Denmark (2008), Luxembourg and the Netherlands. On the other hand, average personnel costs were below EUR10.0 thousand per employee in Poland, Lithuania, Latvia and Romania, as well as Bulgaria where the lowest levels were recorded (EUR3.8 thousand per employee). Combining these two indicators gives the wage-adjusted labour productivity ratio, which is a measure of labour productivity that takes into account the very different levels of pay between Member States and activities. The highest such ratios were recorded in Ireland (330.1%), Hungary (199.6%) and Poland (198.2%). The lowest wage adjusted labour productivity ratios in manufacturing were registered in Sweden, Italy and Germany (all around 120%).

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

European enterprise policy is conducted by the Directorate-General for Enterprise and Industry. The European Commission's enterprise policies aim to create a favourable environment for business to thrive within the EU, creating higher productivity, economic growth, jobs and wealth. Policies are aimed at reducing administrative burden, stimulating innovation, encouraging sustainable production, and ensuring the smooth functioning of the EU's internal market.

In March 2010 the [Europe 2020](#) strategy was adopted: this is the EU's strategy for smart, sustainable and inclusive growth. It is a strategy to enhance the competitiveness of the EU and to create more growth and jobs. The latest revision of the [integrated economic and employment guidelines](#) (revised as part of the Europe 2020 strategy) includes a guideline to improve the business and consumer environment and modernise Europe's industrial base. [An integrated industrial policy for the globalisation era](#) was subsequently adopted by the European Commission in October 2010. As a flagship initiative of the Europe 2020 strategy this policy sets out a strategy that aims to boost growth and jobs by maintaining and supporting a strong, diversified and competitive industrial base offering well-paid jobs while becoming less carbon intensive. The strategy puts forward a wide range of actions mixing broad cross-sectoral measures and actions for specific activities. Among the proposed actions are: the creation of framework conditions for sustainable supply and management of domestic primary raw materials; improving resource efficiency by addressing sector-specific innovation performance, for example in advanced manufacturing technologies; and addressing the challenges of energy-intensive activities through actions to improve framework conditions and support innovation.

Meat production and processing statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers the production and processing of meat, corresponding to NACE Group 15.1, which is part of the [food, beverages and tobacco](#) sector. The activities covered in this article are:

- all meat processing stages that follow on from animal rearing; in other words, the activities of slaughtering through to the preparation of meat for final consumption, including fresh, chilled, frozen, processed, dried, salted and smoked meats;
- the treatment of hides and skins, the rendering of fats and the processing of animal offal.

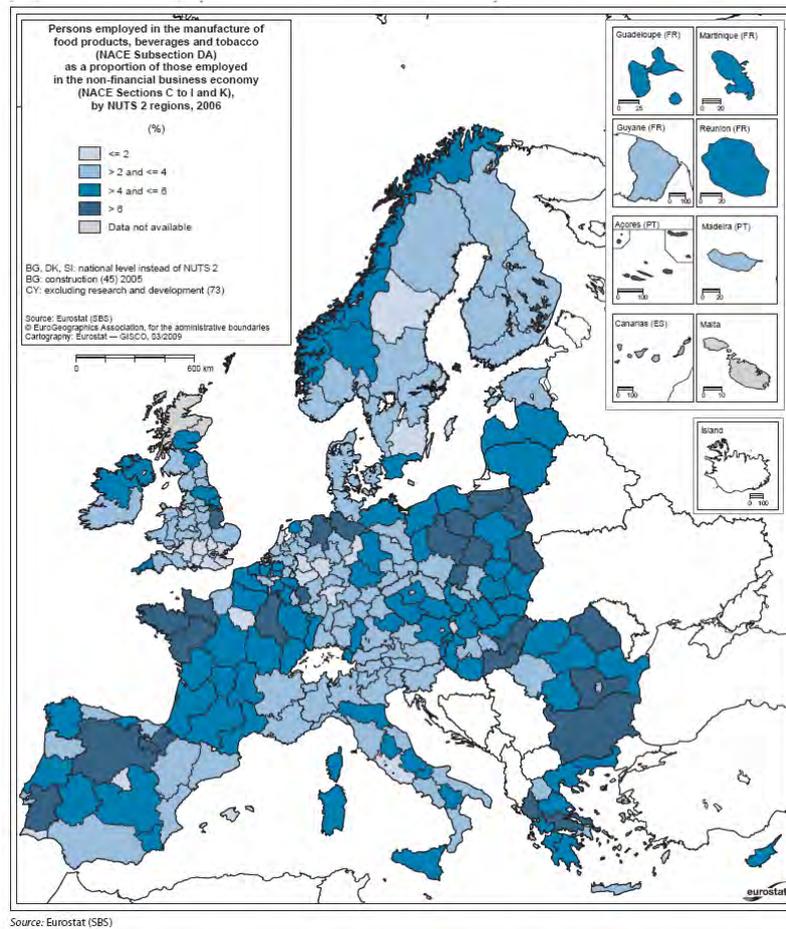

Note that NACE Group 15.1 excludes the agricultural activities of growing, farming, rearing and hunting and also fishing (NACE Divisions 01 and 05).

	Enterprises (thousand)	Turnover (EUR million)	Value added (EUR million)	Persons employed (thousand)	Share in total (%)	
					Value added	Persons employed
Meat and meat products (1)	44.0	175 613	30 000	1 000.0	100.0	100.0

Table 3: Production, processing, preserving of meat, meat products (NACE Group 15.1). Expenditure and productivity, EU-27, 2006

Main statistical findings

Structural profile

There were 44 thousand enterprises across the EU-27 for whom the production, processing and preserving of meat and meat products (NACE Group 15.1, hereafter termed the meat processing sector) was their main area of activity in 2006. These enterprises generated an estimated EUR 30.0 billion of value added in 2006, representing 15.3% of the food, beverages and tobacco manufacturing sector. The meat processing sector was even more significant in terms of employment; an estimated one million persons worked in these activities in 2006, which was equivalent to 21.3% of the food, beverages and tobacco manufacturing sector.

Within the EU-27's meat processing sector, the largest activity in terms of both value added and employment was the production of meat and poultry products (NACE Class 15.13); it generated about 60% of value added and employed over half (54.2%) of the workforce. About one third of sectoral employment (31.7%) and value added (32.1%) could be attributed to the production and preserving of meat (NACE Class 15.11) subsector, the rest coming from the production and preserving of poultrymeat products (NACE Class 15.12) subsector.

In terms of value added, the meat processing sector was, both in absolute and relative terms, particularly important within the German economy. It accounted for 22.6% of the EU-27's value added in 2006, while meat processing enterprises in France and the United Kingdom generated together a further third (32.9%).

Across the EU-27 as a whole, the meat processing sector accounted for just 0.5% of the value added generated within the non-financial business economy in 2006. Relative specialisation was highest in Denmark, at twice the EU-27

average. In terms of employment, Poland was also relatively specialised in meat processing activities, as the 125.0 thousand persons in the workforce in 2005 represented approximately 1.6% of the Polish non-financial business economy workforce, which was twice the average rate in the EU-27.

Apart from a relatively small decline in 2001, the output of the meat processing sector rose steadily during the ten years through until 2007 (with average growth of 1.7% per year). Among the Member States, there was particularly strong output growth over the period considered in Latvia (8.6% per year), Belgium (5.3% per

year), Greece and Poland (both 5.1% per year).

Expenditure and productivity

The Operating costs structure (broken down into personnel costs and purchases of goods and services) of the meat processing sector in the EU-27 was similar to that for the whole of food, beverages and tobacco manufacturing. This was not always the case among the Member States: for example, in Luxembourg [personnel costs](#) accounted for a much higher share of total operating costs for meat processing activities (31.3% compared with 21.0%), while in Cyprus the opposite was true (9.2% compared with 20.1%).

The apparent [labour productivity](#) of the EU-27's meat processing sector was estimated at EUR 30.0 thousand per person employed in 2006. This was the lowest level of labour productivity among the ten NACE groups that comprise the food, beverages and tobacco manufacturing sector and well below the sectoral average of EUR 41.8 thousand per person employed. Despite relatively low average personnel costs (EUR 22.2 thousand per employee, almost 15% less than the food, beverages and tobacco manufacturing average), the Wage adjusted labour productivity ratio of the EU-27's meat processing sector (134.1% in 2005) remained significantly below that for the whole of the food, beverages and tobacco sector (163.0% in 2005).

For the overwhelming majority of Member States, wage adjusted labour productivity within the meat processing sector was relatively low (when compared with the whole of the food, beverages and tobacco manufacturing sector). The two main exceptions concerned meat processing activities in Bulgaria (274.7% compared with 213.4%) and Cyprus (193.5% compared with 146.6%).

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include [short-term statistics \(STS\)](#) .

Context

The food, beverages and tobacco manufacturing sector in the EU is comprised of a relatively small number of enterprises that have a considerable global market presence, which operate alongside a high number of relatively small enterprises that serve more local, regional and national markets.

As these enterprises not only produce goods for final consumption but also intermediate products for other manufacturing activities, they are affected by a broad scope of legislation. The main legislative areas affecting the EU's food, beverages and tobacco manufacturing sector, however, tend to involve international trade agreements, or food and feed legislation. As a majority of the EU's agricultural production is processed by the [food, beverages and tobacco manufacturing sector](#) , developments in [Common Agricultural Policy](#) and associated Common Market Organisations can have important implications for costs and processes in the food chain. Regarding food legislation, the [European Parliament](#) and the [Council](#) proposed an update of the laws regarding the provision of information to consumers in 2008, in order to clarify and consolidate existing regulations. In part, this proposal was built on a 2007 White Paper covering a Strategy for Europe on Nutrition, Overweight and Obesity ([COM\(2007\) 279 final](#)), which stressed the need for consumers to have access to clear, consistent and evidence-based nutritional information.

In recent years, the EU has been active in harmonising animal health measures and systems of disease surveillance, diagnosis and control. It has developed a harmonised legal framework for trade in live animals and animal products. In part, this has been in response to consumer concerns regarding public health and food safety aspects of animal health. In this regard, the European Commission established a framework for animal health and welfare measures for the period 2007-2013 ([COM\(2007\) 539 final](#)). The European Commission also made a proposal to the Council in September 2008 regarding improvements in conditions for animals at the

time of slaughter or killing in order to ensure that they are humanely treated ([COM\(2008\) 553 final](#)).

As well as policies that affect EU production and processing, the European Commission has also laid down new requirements for imports of meat and meat products that are aimed at maintaining and reinforcing standards, such as new rules that came into force in January 2009 concerning poultry and certain [poultry products](#) .

Media and communications statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article introduces a [set of statistical articles](#) which analyse the structure, development and characteristics of the economic activities in the media and communications sector in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), this sector covers NACE Divisions 22 and 64. It focuses on activities whose principal characteristic is to provide services related to the exchange of information. It includes the industrial activities of publishing, printing, and the reproduction of recorded media (NACE Division 22), as well as postal, courier and telecommunication services (NACE Division 64). Its activities are treated in more depth in four further articles:

- [Publishing](#) ;
- [Printing and reproduction](#) ;
- [Post and courier sector](#) ;
- [Telecommunication sector](#) .

	Enterprises		Turnover		Value added		Persons employed	
	(% of (thousand) total)	(% of total)	(EUR million)	(% of total)	(EUR million)	(% of total)	(thousand)	(% of total)
Media and communications	293.2	100.0	792 335	100.0	349 663	100.0	4 857.3	100.0

Table 6: Post and telecommunications (NACE Division 64). Main indicators, 2006 (1)

Main statistical findings

Structural profile

There were 293.2 thousand enterprises in the EU-27's media and communications (NACE Divisions 22 and 64) sector in 2006, which together employed 4.9 million persons. Paid employees accounted for 95.0% of the workforce in 2006, a working status that was dominant when compared with the equivalent share for the non-financial business economy average (86.5%, NACE Sections C to I and K). The share of paid employees was particularly high in the post and telecommunications activities (NACE Division 64) and publishing (NACE Group 22.1), indicating a very low share of working proprietors and unpaid family workers in these activities, unsurprising given the dominance of very large enterprises. The enterprises in the media and communications sector generated EUR 792.3 billion of turnover resulting in EUR 349.7 billion of value added. Apparent labour productivity was high in these activities as they accounted for 6.2% of total value added in the non-financial business economy but just 3.7% of employment.

With EUR 200 billion of value added, telecommunications (NACE Group 64.2) was the largest media and communications subsector in 2006, accounting for over half (57.2%) of the total, followed by post and courier activities (NACE Group 64.1) with a 17.2% share. The two smaller subsectors, publishing (NACE Group 22.1), as well as printing and reproduction of recorded media (NACE Groups 22.2 and 22.3) each contributed around 14%. In employment terms the situation was very different. Post and courier activities had the largest workforce, close to two fifths (38.4%, 2005) of the media and communications total, more than double its value added share. Printing and the reproduction of recorded media also had a higher share of this sector's workforce, as did publishing to a lesser extent. Consequently, the telecommunications workforce accounted for just one quarter of the sectoral total in 2005, approximately half of the share this subsector recorded in terms of value added.

Germany and the United Kingdom were the largest Member States in the media and communications sector in 2006, both accounting for around one fifth of the EU-27's value added. In employment terms, Germany's share was slightly larger, while that of the United Kingdom was significantly smaller. Looking at the contribution of this sector within the non-financial business economy, the most specialised Member State⁷⁹ in value added terms was Bulgaria (2005), where media and communications activities contributed just over one tenth of non-financial business economy value added; in fact this sector was the second largest sector (in terms of all the structural business statistics sectors) in Bulgaria. The sector was quite important in all Member States, as even in Austria, the least specialised Member State in 2006, it accounted for 4.6% of non-financial business economy value added.

The regional specialisation of these activities is shown in the map which is based on the non-financial business economy employment share of this sector. Countries with many regions specialised in these activities include the United Kingdom, Germany, the Netherlands, Belgium, the Nordic countries and Slovakia. These activities were often particularly centred in or around the capital, with the capital region in 15 of the 18 multi-regional Member States (with data available) being among the most specialised regions (more than 4% of the workforce in this activity). The main exception to this was Germany, as the capital region of Berlin was not particularly specialised in media and communications; in another German region however, Köln, this sector accounted for 25.3% of non-financial business economy employment, making this the single most specialised region in media and communications among all of the regions in the EU.

Annualised short-term statistics are available for the EU-27 starting in 1998 (employment) and 2000 (turnover) for the services activities of post and telecommunications, while a longer series is available for the industrial activity of publishing, printing, and the reproduction of recorded media (NACE Division 22). Looking first at turnover, post and courier activities (NACE Group 64.1) and telecommunications (NACE Group 64.2) both developed strongly since 2000, averaging growth of 4.1% per year for post and courier activities up to 2007 and 6.1% per year for telecommunications in the EU-27. In contrast, the turnover index for publishing, printing, and the reproduction of recorded media grew on average by 1.8% per year over the same period, only exceeding this average on two occasions, 2004 (4.1%) and 2006 (2.9%).

In employment terms, two phases of development could be observed for post and telecommunications as well as for publishing, printing, and the reproduction of recorded media: both activities showed a period of growth until 2001, followed by a reduction in employment levels. Between 2001 and 2007, the average annual fall for the employment index for publishing, printing, and the reproduction of recorded media was -1.6%, while for post and telecommunications it was -2.1%. As such, post and telecommunications was one of only two services sectors (along with air transport) that recorded a reduction in employment during this period.

⁷⁹Bulgaria, Cyprus, Poland and Romania, 2005; Luxembourg, Malta and the Netherlands, not available.

Large enterprises (with 250 and more persons employed) were predominant in the EU-27's media and communications sector as they contributed more than three quarters of total value added generated in this sector in 2006 and occupied close to two thirds of the workforce. Post and telecommunications was dominated by large enterprises, as these accounted for 92.4% of sectoral value added in the EU-27. This was the highest proportion of value added accounted for by large enterprises across all non-financial services (NACE Sections G to I and K) NACE divisions⁸⁰ in 2006. In contrast, the value added share of large enterprises in publishing, printing and the reproduction of recorded media was 41.2%, marginally below the non-financial business economy average. The share of value added generated by **micro enterprises** (with less than 10 persons employed) in publishing, printing and the reproduction of recorded media (14.6%) was also below the non-financial business economy average (21.0%, 2005). As a result, **small enterprises** (with between 10 and 49 persons employed), and particularly **medium-sized enterprises** (with between 50 and 249 persons employed) made a relatively high contribution within the publishing, printing and the reproduction of recorded media activities.

Employment characteristics

Labour force statistics show that the characteristics of the workforce in the EU-27's media and communications sector (NACE Divisions 22 and 64) did not diverge greatly from those for the non-financial business economy as a whole. Indeed, about three fifths (60.6%) of the sectoral workforce were men in 2007, a proportion slightly lower than that for the non-financial business economy as a whole (64.9%). The proportion of part-time employment in the sector was 17.0% in 2007, compared with 14.4% for the non-financial business economy. A breakdown by age of the workforce for the EU-27's media and communications sector shows that younger workers (aged 15 to 29) accounted for a lower proportion of the workforce than in the non-financial business economy as a whole, with slightly higher proportions for the two other age groups.

Expenditure, productivity and profitability

In 2006, the EU-27 media and communications sector undertook **tangible investments** to the value of EUR 57.7 billion, equivalent to 5.6% of the total for the non-financial business economy. As this was slightly lower than the sector's share of value added, the **investment rate** for media and communications (16.5%) was below the non-financial business economy average (18.4%). The vast majority of this investment was recorded for telecommunications, which consequently had the highest investment rate (24.3%, 2005). Post and courier activities as well as publishing both recorded particularly low investment rates – these being the fifth and seventh lowest rates among all NACE divisions in the non-financial business economy (with data available for 2005 or 2006). Romania, Cyprus (both 2005) and the United Kingdom were the only Member States⁸¹ where the investment rate for media and communications was higher than the non-financial business economy average.

The share of **personnel costs** in operating expenditure was also considerably higher for the EU-27's media and communications sector (27.1%) than for the non-financial business economy as a whole (16.1%). This was the case in all of the subsectors that make up the media and communications sector, where the share of total expenditure dedicated to personnel costs was lowest at 19.9% (2005) for telecommunications and reached as high as 53.9% (2005) for post and courier activities, the fourth highest share among all NACE groups within the non-financial business economy (in 2005 or 2006). This high share of personnel costs for media and communications was observed in all the Member States with data available. Average personnel costs in the EU-27's media and communications sector were EUR 36.9 thousand per employee, which was EUR 8.1 thousand per employee higher than the non-financial business economy average. The only subsector with average personnel costs below the non-financial business economy average was post and courier activities, while the EUR 51.5 thousand per employee average for telecommunications was the highest among the non-financial services (NACE Sections G to I and K) NACE groups.

Apparent labour productivity in the EU-27's media and communications sector was EUR 72.0 thousand per person employed in 2006, which was nearly two thirds higher than the non-financial business economy average. Underlying this was a particularly high apparent **labour productivity** in the telecommunications subsector – the fourth highest among all non-financial business economy NACE groups in 2005 or 2006 – as well as a high productivity in publishing. In contrast, the post and courier activities subsector recorded apparent labour productivity below the non-financial business economy average in 2005.

⁸⁰NACE Divisions 55 and 60, 2005.

⁸¹Bulgaria, Cyprus, Poland and Romania, 2005; Ireland, Luxembourg, Malta and the Netherlands, not available.

The [wage-adjusted labour productivity ratio](#) within the EU-27's media and communications sector (195.0%) in 2006 indicated that apparent labour productivity was close to twice as high as average personnel costs. Again it was the telecommunications sector that recorded the highest ratio, 309.4% in 2005. Among the Member States⁸² only Denmark recorded a lower wage-adjusted labour productivity ratio for media and communications than for the non-financial business economy as a whole. In a similar manner, the gross operating rate for the EU-27's media and communications sector stood at 22.6% in 2006, which was more than twice the non-financial business economy average (10.8%); once more the highest rate among the subsectors was recorded for telecommunications (30.8%, 2005).

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include [short-term statistics \(STS\)](#) and the [Labour force survey \(LFS\)](#) .

Context

This sector gathers together several activities linked to media and communication activities, however, within this group a distinction has to be made between traditional activities (for example, postal services) for which the level of activity is rather stable and other newer activities (such as mobile telephony and electronic publishing), for which growth developments are more marked.

Metal casting statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). The present article covers metal casting, corresponding to [NACE Rev 1.1 Group 27.5](#), which is part of the [metals and metal products](#) sector. The activities covered in this article include a range of metals (including iron, steel, light metals and other non-ferrous metals), and involves the manufacture of semi-finished castings for downstream customers.

The information presented does not include the manufacture of standardised, finished products (such as tubes, see [Iron and steel production and processing statistics - NACE Rev. 1.1](#)) or boilers or radiators (see [Boilers, metal containers and steam generators production statistics - NACE Rev. 1.1](#)).

Note also that there are no external trade statistics for foundry work services ([CPA Group 27.5](#)).

	Highest value added (1)		Largest number of persons employed (2)		Most specialised: share in non-financial business economy (%) (3)

 Source: Eurostat (SBS).

Table 2: Casting of metals (NACE Group 27.5). Expenditure, productivity and profitability, EU-27, 2006 (1)

The activity of the casting of metals (NACE Group 27.5) was carried out by 6.7 thousand [enterprises](#) across the [EU-27](#) in 2006. From a [turnover](#) of EUR 37.6 billion, these enterprises generated EUR 11.8 billion of [added value](#) in 2006, which was the smallest contribution (4.8%) to the value added of the metals and metal products manufacturing (NACE Subsection DJ) sector. The casting of metals sector employed an estimated 270.0 thousand persons in the Member States in 2006, about one in every twenty (5.3%) of the EU-27's metals and metal products manufacturing workforce which was a slightly higher share than that recorded for basic precious and non-ferrous metals (NACE Group 27.4).

The casting of iron (NACE Class 27.51) and the casting of light metals (NACE Class 27.53) were the two largest activities within the casting of metal, together providing about three quarters (73.3%) of the EU-27's value added in 2006.

Germany generated more value added than any other Member State for most of the subsectors of the metals and metal products sector; its share of EU-27 value added was highest, however, for the casting of metals (36.8%).

By way of comparison, this was almost exactly the same share of value added as came from the next three largest Member States combined – Italy (16.2% of EU-27 value added), France (10.6%) and Spain (10.1%). However, the proportional contribution made by this sector to non-financial business economy value added in 2006 was highest in Slovenia (0.8%), where it was almost four times the average size within the EU-27. In these terms, the Czech Republic and then Germany were the next most specialised Member States⁸³ for the casting of metals.

There was a very close match between the development of the EU-27's [production index](#) for metals and metal products manufacturing and that for the casting of metals in the period between 1997 and 2007. Over the ten-year period as a whole, the output of the casting of metals in the EU-27 rose by an average 1.8 per year.

Expenditure and productivity

Although [tangible investment](#) of EUR 1.7 billion in the casting of metal sector represented only 5.1% of tangible investment across all metals and metal products manufacturing activities in 2006, this was a higher proportion than this sector's contribution to value added. In these relative terms, therefore, the EU-27 [investment rate](#) (14.3%) for the casting of metals sector was slightly higher than the rate (13.6%) for metals and metal products manufacturing. Average personnel costs in the EU-27's casting of metals sector were EUR 33.0 thousand per employee in 2006, an almost identical figure to the average for all metals and metal products manufacturing. As a proportion of [operating expenditure](#), however, personnel costs in the casting of metals sector accounted for a relatively high share (24.5%) both in comparison to metals and metal products manufacturing (19.2%) and more particularly the [non-financial business economy](#) (16.1%).

The average amount of added value generated by each person in the EU-27's casting of metals sector was EUR 43.7 thousand in 2006, about one tenth (9.3%) less than the average for the whole of the metals and metal products manufacturing sector. With similar average personnel costs in 2006, the [wage-adjusted labour productivity ratio](#) (132.3%) for the casting of metals sector remained a similar proportion below the ratio (149.3%) for all metals and metal products manufacturing. This relatively low wage-adjusted labour productivity ratio was a feature of the four NACE classes within the casting of metals sector. It was also a characteristic common to the majority of the Member States, the principal exception being in Ireland where the ratio for the casting of metals sector was significantly higher than the ratio across all metals and metal products manufacturing.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Context

The metals and metal products manufacturing sector is part of a diverse and interwoven economic network that incorporates upstream sectors and large downstream segments of manufacturing such as the transport equipment manufacturing and construction sectors. The challenges faced by the EU's metals and metal products manufacturing sector therefore have direct and indirect consequences on many other parts of the economy. Looking ahead, a Communication ([COM\(2008\) 108](#)) from the [European Commission](#) to the [Council](#) and the [European Parliament](#) on the competitiveness of the metals industries was adopted in February 2008, and highlighted the challenges to be faced.

The EU-27 is largely dependent on imports of ore and concentrates for steel, ferro-alloys and non-ferrous metals production; it produces only 1.7% of the world's nickel, 2% of its iron ore and 5% of its copper ([SEC\(2007\) 771](#)). Access to minerals and secondary raw materials at competitive prices is important, especially given the exhaustion of certain deposits in the EU-27 over time or their absence, and supply constraints that have been exacerbated by the strong growth in international demand from emerging economies such as China and India. This concern was part of a raw materials initiative of the European Commission ([COM\(2008\) 699](#)).

⁸³Bulgaria, Cyprus, Poland, Portugal and Romania, 2005; Latvia, Malta and the Netherlands, not available.

Parts of the metals and metal products manufacturing sector are highly [energy-intensive](#) . Energy costs for the EU-27's metals and metal products manufacturing sector accounted for 4.4% of purchases of goods and services in 2006, which was the third joint highest proportion among the industrial structural business statistics sectors, albeit well behind non-energy mining and quarrying (10.1%) and other nonmetallic mineral products (9.5%). Within this sector, however, energy costs in the casting of metals subsector accounted for 7.2% of purchases of goods and services in 2006 and in the first processing of ferrous metals as much as 7.9%. This level of energy consumption has important implications for energy and environmental (particularly climate change) policy.

The metals and metal products manufacturing sector is covered by a Directive on [integrated pollution prevention and control \(IPPC\)](#) and [REACH](#) . A proposal from the European Commission on the review of EU [Emissions trading system \(ETS\)](#) adopted in January 2008 ([COM\(2008\) 30](#)) foresees the inclusion of non-ferrous metals from 2013 onwards, along with some transitional measures to avoid 'carbon leakage'.

Notes

Metals and metal products statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article introduces a [set of statistical articles](#) which analyse the structure, development and characteristics of the economic activities in the metals and metal products sector in the [European Union \(EU\)](#) . This sector corresponds with two [NACE Rev 1.1](#) divisions:

- the manufacture of basic metals (NACE Division 27);
- the downstream activity of the manufacture of fabricated metal products (NACE Division 28).

The activities of this sector are treated in more depth in seven further articles, the first three of which cover NACE Division 27, and the last four of which cover NACE Division 28:

- [Iron and steel production and processing statistics](#) , which covers the manufacture of iron, steel and ferro-alloys (NACE Groups 27.1 to 27.3);
- [Precious and non-ferrous metal production statistics](#) , which covers the manufacture of basic precious and non-ferrous metals (NACE Group 27.4);
- [Metal casting statistics](#) , which covers the first processing stages of metal manufacturing (such as the manufacture of tubes, bars, strips, wires, and sheets of metal, as well as casting) (NACE Group 27.5);
- [Structural metal products manufacturing](#) , which covers metal supports and structures, prefabricated buildings, metal doors, window frames and shutters (NACE Group 28.1);
- [Boilers, metal containers and steam generators production](#) , which covers metal tanks, reservoirs and containers, and central heating radiators and boilers (NACE Group 28.2), as well as steam generators, for example, vapour generators, condensers and nuclear reactors (NACE Group 28.3);
- [Forging, metal coating and mechanical engineering](#) , which covers the forging, pressing, stamping and roll forming of metal (NACE Group 28.4), as well as the treatment and coating of metal and general mechanical engineering (such as turning, milling, or welding) (NACE Group 28.5);
- [Fabricated metal product manufacturing](#) , which covers the manufacture of cutlery, tools and general hardware (NACE Group 28.6), as well as the manufacture of other fabricated metal products (such as metal drums, metal packaging, wire products, and household articles of metal) (NACE Group 28.7).

This article does not include the manufacture of machinery and equipment, which is covered separately in the article on [Machinery and equipment production statistics - NACE Rev. 1.1](#) .

Note that there are no external trade statistics for a number of industrial services covered in these articles, namely foundry work services ([CPA](#) Group 27.5), forging, pressing, stamping and roll forming metal services ([CPA](#) Group 28.4) and treatment and coating of metal services and general mechanical engineering services ([CPA](#) Group 28.5).

	Enterprises		Turnover		Value added		Persons employed	
	(% of (thousand)	total)	(EUR million)	(% of total)	(EUR million)	(% of total)	(thousand)	(% of total)

Table 6: Manufacture of fabricated metal products, except machinery and equipment (NACE Division 28). Main indicators, 2006 (1)

There were 417.7 thousand enterprises throughout the Member States for which metal and metal products manufacturing (NACE Subsection DJ) was their principal activity in 2006. In terms of both the number of persons employed and value added generated the EU-27's metals and metal products manufacturing sector was the largest sector among the industrial (NACE Sections C to E) structural business statistics sectors. The sector employed almost 5.1 million persons across the EU-27 in 2006, corresponding to 3.9% of the workforce within the non-financial business economy (NACE Sections C to I and K). The proportion of paid employees among the number of persons employed by the metals and metal products manufacturing sector was 92.2% in 2006, a higher proportion than across the non-financial business economy as a whole (86.5%). From a turnover of EUR 863.7 billion in 2006, the EU-27's metal and metal products sector created EUR 244.4 billion of added value, a 4.3% contribution towards the value added of the non-financial business economy.

The largest subsector (in terms of the different groups of metals and metal products) was forging, metal coating and mechanical engineering (NACE Groups 28.4 and 28.5, as presented in [Forging, metal coating and mechanical engineering statistics - NACE Rev. 1.1](#)), which contributed about one quarter of value added (24.6%) and employment (28.2%). The manufacture of miscellaneous fabricated metal products (NACE Groups 28.6 and 28.7, as presented in [Fabricated metal product manufacturing statistics - NACE Rev. 1.1](#)) subsector and the first processing of ferrous metal (NACE Groups 27.1 to 27.3, as presented in [Iron and steel production and processing statistics - NACE Rev. 1.1](#)) each provided a further one fifth (in both cases 20.3%) of the value added within this sector in 2006, although the former was much larger than the latter in terms of employment (21.9% of the metals and metal products workforce compared with 12.1%). The second largest subsector in terms of employment was the manufacture of structural metal products (NACE Group 28.1, as presented in [Structural metal products manufacturing statistics - NACE Rev. 1.1](#)), which accounted for a little over one fifth of all employment (22.0%), although it was only the fourth largest subsector in terms of value added (accounting for 16.7%). The other subsectors presented in [Precious and non-ferrous metal production statistics - NACE Rev. 1.1](#) , [Metal casting statistics - NACE Rev. 1.1](#) and [Boilers, metal containers and steam generators production statistics - NACE Rev. 1.1](#) , each accounted for less than 7.5% of sectoral employment or value added.

Among the Member States, the metals and metal products manufacturing sector in Germany was the largest, generating EUR 64.9 billion of added value in 2006, a little over one quarter (26.6%) of the EU-27 total. In these terms, the metals and metal products manufacturing sectors were next largest in Italy (16.3% of EU-27 value added) and France (11.9%). The Member State most specialised in the manufacture of metals and metal products was Slovakia, however, where the contribution of metals and metal products manufacturing to the total value added of the non-financial business economy was 9.0% in 2006, just over twice the EU-27 average. There was also strong specialisation in this activity in Slovenia and the Czech Republic.

The metal and metal products manufacturing sector provided relatively high levels of [employment](#) in a number of regions across the EU-27 in 2006; representing more than one in every ten workers within the regional non-financial business economies of Norra Mellansverige (Sweden), Arnsberg, Gießen and Saarland (all Germany), Moravskoslezsko (the Czech Republic), Východné Slovensko (Slovakia) and País Vasco (Spain). There were several countries where a large share of the regions were relatively specialised in these activities.

The annual development of the EU-27 [production index](#) for metals and metal products manufacturing during the ten years through until 2007 was very similar to the development of [output](#) for industry (NACE Sections C to E) as a whole; between 1997 and 2007, the average rate of growth in both indices was 2.1% per year.

The average EU-27 rate of growth in the output of the manufacture of fabricated metal products (NACE Division 28) during the ten years through until 2006 was much stronger (2.7% per year) than that (1.1% per year) recorded for the manufacture of basic metals (NACE Division 27). Among the dozen NACE groups that comprise metal and metal products manufacturing, the strongest rates of growth in output concerned the two other metal processing activities (see [Forging, metal coating and mechanical engineering statistics - NACE Rev. 1.1](#)); the annual average rate of growth in the output of the treatment and coating of metal and general mechanical engineering (NACE Group 28.5) was 4.4% per year and that of the forging, pressing, stamping and roll forming of metals (NACE Group 28.4) was 4.2% per year.

The development of the EU-27's domestic output price index for metals and metal products manufacturing during the ten years between 1997 and 2007 reflected three distinct periods; firstly, there were relatively stable prices between 1997 and 1999, secondly, there was a rise in 2000 to a new plateau that was maintained through 2001 and 2002, and finally there was a strong upsurge in prices through until 2007. This was also the broad development for industrial output prices as a whole. The rise in the domestic [output price index](#) for metals and metal products between 1997 and 2002 averaged 0.7% per year but the index rose on average by 5.7% per year in the last five years of the period under review, partly reflecting price increases for raw materials and energy. The rise in the domestic output price of basic metals (NACE Division 27) was particularly strong, rising 9.6% per year on average in the five years through to 2007.

Against this background of strongly rising output and domestic output prices for metals and metal products in the period between 2003 and 2007, there was a partial reversal in the downward trend in the [index of employment](#) for metals and metal products manufacturing. Over the ten years through to 2007, the EU-27 index of employment for metals and metal products manufacturing declined by an average 0.2% per year, which was much less than the average rate of decline (-1.2% per year) across the whole of industry. Indeed, nearly every other industrial NACE subsection reported a stronger fall in the employment index over this period, with the low growth (0.7%) in rubber and plastics manufacturing (NACE Subsection DH) and no change in transport

equipment manufacturing (NACE Subsection DM) the only exceptions.

Small and medium-sized enterprises (SMEs) , which employ less than 250 persons, generated the majority (61.2%) of value added in the EU-27's metals and metal products manufacturing sector in 2006. Within the sector, however, there was a distinct difference between the dominance of **large enterprises** (that employ 250 persons or more) in the manufacture of basic metals (accounting for 74.2% of the value added generated by this activity) and the dominance of SMEs in the manufacture of fabricated metal products (accounting for 78.3% of value added). This dichotomy placed these two activities at odds with the average situation across the non-financial business economy, for which SMEs contributed a relatively small majority (57.9%) of value added. These structural differences were also apparent in terms of relative shares of employment.

Employment characteristics

In 2007, a little more than eight in every ten workers (84.5%) within the EU-27's metals and metal products manufacturing sector were male, a much higher share than that across the non-financial business economy as a whole (64.9%). This was a characteristic that was noted across all of the Member States for which information is available⁸⁴. An above average proportion of those working (94.7%) in the EU-27's metals and metal products manufacturing sector were in full-time employment, a characteristic that was more similar to the situation across industry as a whole (an average of 92.7% being male) than the non-financial business economy (an average of 85.7%). This was also a characteristic generally noted among the Member States.

The proportion of young workers aged 15 to 29 years old in the metals and metal products manufacturing sector was somewhat lower than the average across the EU-27's non-financial business economy (21.6% compared with 24.3%), the difference being made up for in the proportion of workers aged 50 or more (24.5% compared with 21.9%). Among the Member States, the share of young workers in the metals and metal products manufacturing sector was disproportionately low in the Netherlands, Romania and the United Kingdom, being about one third less than the corresponding share of this age group within their respective non-financial business economies.

Expenditure, productivity and profitability

Four fifths (80.8%) of **operating expenditure** in the EU-27's metals and metal products manufacturing sector went on goods and services in 2006, although this was a little less than the average share (83.9%) across the non-financial business economy. The remaining share (19.2%) of operating expenditure went on **personnel costs** , however, there were stark differences between the two metals and metal products manufacturing NACE divisions; personnel costs in the EU-27's manufacture of fabricated metal products activity accounted for just over a quarter (25.8%) of operating expenditure in 2006, more than twice the proportion (11.6%) recorded for the EU-27's manufacture of basic metals activity, despite the fact that average personnel costs in the former were about EUR 10.0 thousand per employee less than the average for the manufacture of basic metals (EUR 39.6 thousand per employee in 2006). In this way, the metals and metal products manufacturing sector comprised one relatively capital-intensive activity and one relatively labour-intensive, low-paid activity. Average personnel costs in the EU-27's metals and metal products manufacturing sector were EUR 32.2 thousand per employee in 2006, some 11.8% more than the non-financial business economy average.

Tangible investment across the EU-27 in the metals and metal products manufacturing sector was EUR 33.4 billion in 2006, which corresponded to 3.2% of all tangible investment in the EU-27's non-financial business economy. This proportion was less than the equivalent proportion in value added terms, resulting in an **investment rate** within the metals and metal products manufacturing sector (13.6%) that was well below the average for the non-financial business economy (18.4%).

Each person employed within the EU-27's metals and metal products manufacturing sector generated an average EUR 48.1 thousand of value added in 2006, about a tenth more than within the non-financial business economy as a whole. Although the apparent **labour productivity** of this sector more than covered its average personnel costs, the **wage-adjusted labour productivity ratio** of 149.3% was a little lower than that recorded for the whole of the non-financial business economy (151.1%). Within the metals and metal products manufacturing sector, the wage-adjusted labour productivity ratio of the EU-27's basic metals manufacturing activity (182.1%) was

⁸⁴Malta, not available.

much higher than the ratio for the fabricated metal products activity (137.9%) in 2006.

The [gross operating rate](#) shows the relationship between the gross [operating surplus](#) (value added minus personnel costs) and turnover in percentage terms, and is a measure of operating profitability. The gross operating rate of the EU-27's metals and metal products manufacturing sector was 10.8% in 2006, the same average rate as recorded for the non-financial business economy. Within this sector, the operating profitability of the fabricated metal products activity (12.1%) was substantially higher than the rate for the basic metals manufacturing activity (9.3%).

External trade

Total ([intra-](#) and [extra-EU](#)) [exports](#) of metal and fabricated metal products (CPA Subsection DJ) by the EU-27 Member States were valued at EUR 393.3 billion in 2007, while [imports](#) were larger, a total of EUR 409.9 billion. Exports (intra- and extra-EU) of metals and fabricated metal products from Germany were valued at EUR 94.7 billion in 2007, accounting for a little less than one quarter (24.1%) of all exports of these products by EU-27 Member States. Among the Member States, Germany also had the largest [trade surplus](#) (EUR 9.1 billion) in metal and fabricated metal products, although it was much lower than the surplus it had recorded two years earlier (EUR 13.3 billion). Other sizeable trade surpluses in 2007 were recorded for Belgium (EUR 4.5 billion), Sweden, the Netherlands, Austria, Slovakia, Luxembourg and Finland (all between EUR 1.2 billion and EUR 2.3 billion). In contrast, Spain and Italy had the largest [trade deficits](#) for these products (EUR 8.0 billion and EUR 6.5 billion respectively). It is also worth noting that the share of metals and fabricated metal products exports in national industrial (CPA Sections C to E) exports was highest in Bulgaria (26.1%), where such goods accounted for the highest proportion of industrial exports (at the level of CPA subsections), and Luxembourg (25.8%), where they accounted for the second highest proportion of industrial exports after electrical and optical equipment (CPA Subsection DL).

Almost three quarters (74.0% based on export values) of Member States' trade in metal and metal products was with other Member States (so-called intra-EU trade), which represented a much higher proportion than the average (67.6%) for all industrial products.

Focusing on trade with non-member countries (so-called extra-EU trade), the EU-27 recorded a trade deficit of EUR 24.8 billion for metals and fabricated metal products in 2007. This trade deficit reflected a significant turnaround from the situation in 2005 when the EU-27 had reported a trade surplus of EUR 3.3 billion. The underlying feature of this turnaround was the growth in the value of imports from non-member countries from EUR 72.9 billion in 2005 to EUR 126.9 billion in 2007, the highest shares of which came from China (leaping to 16.3% in 2007) and Russia (down to 11.1%). This growth was much stronger than that for the value of EU-27 exports of metals and fabricated metal products, which increased to EUR 102.1 billion in 2007, accounting for 8.8% of industrial exports.

The EU-27's trade deficit in metals and fabricated metal products in 2007 was dominated by the trade deficit of EUR 32.2 billion for basic metals (CPA Division 27), there being a trade surplus of EUR 7.4 billion for fabricated metal products (CPA Division 28).

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include [short-term statistics \(STS\)](#) and the [COMEXT](#) database for external trade,

Context

The metals and metal products manufacturing sector is part of a diverse and interwoven economic network that incorporates upstream sectors and large downstream segments of manufacturing such as the transport equipment

manufacturing and construction sectors. The challenges faced by the EU's metals and metal products manufacturing sector therefore have direct and indirect consequences on many other parts of the economy. Looking ahead, a [Communication COM\(2008\) 108](#) from the [European Commission](#) to the [Council](#) and the [European Parliament](#) on the competitiveness of the metals industries was adopted in February 2008, and highlighted the challenges to be faced.

The EU-27 is largely dependent on imports of ore and concentrates for steel, ferro-alloys and non-ferrous metals production; it produces only 1.7% of the world's nickel, 2% of its iron ore and 5% of its copper ([SEC\(2007\)771](#)). Access to minerals and secondary raw materials at competitive prices is important, especially given the exhaustion of certain deposits in the EU-27 over time or their absence, and supply constraints that have been exacerbated by the strong growth in international demand from emerging economies such as China and India. This concern was part of a [raw materials initiative COM\(2008\) 699](#) of the European Commission.

Parts of the metals and metal products manufacturing sector are highly [energy-intensive](#) . Energy costs for the EU-27's metals and metal products manufacturing sector accounted for 4.4% of purchases of goods and services in 2006, which was the third joint highest proportion among the industrial structural business statistics sectors, albeit well behind non-energy mining and quarrying (10.1%) and other nonmetallic mineral products (9.5%). Within this sector, however, energy costs in the casting of metals subsector accounted for 7.2% of purchases of goods and services in 2006 and in the first processing of ferrous metals as much as 7.9%. This level of energy consumption has important implications for energy and environmental (particularly climate change) policy.

The metals and metal products manufacturing sector is covered by a Directive on Integrated Pollution Prevention and Control (IPPC) and [REACH](#) . A [proposal COM\(2008\) 30](#) from the European Commission on the review of EU [Emissions trading system \(ETS\)](#) adopted in January 2008 foresees the inclusion of non-ferrous metals from 2013 onwards, along with some transitional measures to avoid 'carbon leakage'.

Notes

Mining and quarrying statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article presents an overview of statistics for [European Union \(EU\)](#) mining and quarrying, covering [NACE Section C](#). The activities of mining and quarrying are treated in more depth in two specific articles, based on the type of product being mined:

- [energy-producing materials](#) coal, crude petroleum, natural gas or uranium;
- [non-energy-producing materials](#) metal ores, stone, sand, clay, salt, or a range of chemical and fertiliser minerals.

Note that this article only covers *extractive* activities, and not the [processing of fuel](#), the [manufacture of non-metallic mineral products](#), nor the [network supply and distribution of electricity, gas and steam](#).

	Enterprises		Turnover		Value added		Persons employed

Table 3: Mining and quarrying (NACE Section C). Share of value added and persons employed by enterprise size class, EU-27, 2006 (%)

Main statistical findings

Structural profile

There were 20.7 thousand [enterprises](#) operating with mining and quarrying (NACE Section C) as their main activity in the EU-27

in 2006. Together they employed 733.2 thousand persons, equivalent to 0.6% of the [non-financial business economy](#) (NACE Sections C to I and K) [workforce](#), while they generated EUR 88.5 billion of [value added](#) (1.6%). Paid [employees](#) made up 97.9% of all [persons employed](#) (which also includes working proprietors and unpaid family workers) within the EU-27's mining and quarrying sector in 2006, well above the non-financial business economy average (86.5%). Indeed, this proportion rose to 99.6% for the mining and quarrying of energy-producing materials (which was the highest among all industrial NACE subsections), whereas it stood close to the industrial average (94.2%) for non-energy producing materials (95.4%).

The vast majority (88.3%) of the EU-27's mining and quarrying enterprises extracted non-energy producing materials (NACE Subsection CB). However, in economic terms, the relative importance of energy-producing materials (NACE Subsection CA) was far greater, accounting for 78.0% of sectoral value added; in more detail the most important activity (in value-added terms) was the extraction of crude petroleum and natural gas (NACE Division 10), which accounted for approximately two thirds (66.9%) of EU-27 sectoral value added.

It is perhaps therefore not surprising to find that the United Kingdom (with oil and gas fields off its east coast) recorded the highest share (39.5%) of EU-27 value added within the mining and quarrying sector in 2006. Denmark (predominantly natural gas), Italy (crude petroleum and natural gas), Germany and Poland (both coal and lignite) were also relatively important producers within the EU in value added terms. The Polish mining and quarrying workforce of 188.6 thousand persons was equivalent to almost a quarter (24.4%, 2005) of the EU-27 total, and was followed by Romania (17.4%, 2005) and Germany (11.9%).

The relative importance of the mining and quarrying sector tended to be highest among those countries specialised in the extraction of energy-producing materials: the extraction of crude petroleum and natural gas in Romania, Denmark and the United Kingdom, or the mining of coal and lignite in Poland, the Czech Republic, Bulgaria and Romania. This is perhaps not surprising given the geological distribution of natural resources – which were scarce or non-existent in many of the remaining Member States. Bulgaria, Romania and Sweden were specialised in the extraction of metal ores, while Bulgaria, Cyprus, Greece and Portugal recorded some of the highest specialisation ratios with respect to other mining and quarrying.

The [enterprise size](#) structure of the mining and quarrying sector would appear to be dominated by [large enterprises](#); however, the overall average is a combination of two extremes. The mining and quarrying of coal and lignite and of metal ores are particularly concentrated in only a few locations and characterised by a high dominance of large enterprises (with 250 or more persons employed); the extraction of crude petroleum and natural gas is also relatively concentrated among large enterprises. Indeed, the mining of coal and lignite and the mining of metal ores were two of only four NACE divisions to report that upwards of 90% of their EU-27 value added was generated by large enterprises ([tobacco manufacturing](#) and [post and telecommunications](#) being the others). On the other hand, the local sourcing of many construction materials and a range of chemical and fertiliser minerals are characterised by widespread availability, relatively high transport costs and low barriers to entry, reflected in a higher degree of importance for [small and medium-sized enterprises](#) (with less than 250 persons employed).

Large enterprises accounted for 64.3% of the total value added generated within the EU-27's mining and quarrying sector in 2006, more than 20 percentage points above the non-financial business economy average. In employment terms, the relative importance of large enterprises was even greater, accounting for 68.1% of the mining and quarrying workforce, compared with an average of 32.6% for the whole of the non-financial business economy. The fact that the employment share of large enterprises was larger than the value added share indicates that large enterprises had a lower apparent [labour productivity](#) than small and medium-sized enterprises (with less than 250 persons employed). This is unusual, in that large enterprises generally display a higher productivity; the situation of this sector is due principally to the particularly low labour productivity among the large enterprises in the mining and quarrying of coal and lignite subsector.

Source: Eurostat (SBS)

Figure 4: Mining and quarrying (NACE Section C). Labour output and costs, EU-27, 2006 (EUR thousand per capita)

The EU-27's mining and quarrying sector is an industry that has been in decline for several decades. The average reduction in output during the period 1997-2007 equated to 2.2% per year. This was entirely due to a decrease in mining and quarrying activity for energy producing materials (average decline of 3.2% per year), as the EU-27 index of production for mining and quarrying of non-energy producing materials rose, on average, by 2.0% per year over the period considered.

Employment losses within the EU-27's mining and quarrying workforce between 1997 and 2007 were substantial, employment falling on average by 5.6% per year compared with an average of 1.2% for industrial activities (NACE Sections C to E). Although the number of persons employed fell every year between 1997 and 2007, the biggest contractions were recorded at the start of the period in 1999 and 2000, when close to 10% of the mining and quarrying workforce was shed each year.

Domestic output prices for the EU-27's mining and quarrying sector show that there was a rapid fall in prices in 1998 (17.6% compared with the year before). The fluctuating nature of prices was however evident two years later, as EU-27 output prices for mining and quarrying rose by 23.5% in 2000, followed by a period of relative calm, before prices rose again at a rapid pace between 2004 and 2006, remaining at historically high levels in 2007. The overall output price index for mining and quarrying reflected closely developments in the index for the mining and quarrying of energy producing materials, although towards the end of the [time series](#) there was also evidence of rapidly rising prices for non-energy producing materials (up 8.1% in 2006); this latter development may be associated with increasing demand for minerals, driven by emerging economies).

Employment characteristics

EU-27 mining and quarrying activities are characterised by a relatively high reliance on full-time, male employment. According to the [Labour force survey](#), 97.3% of those employed in this sector worked on a full-time basis in 2007, one of the highest full-time employment rate of all structural business statistics sectors, and some

11.6 percentage points above the non-financial business economy average (85.7%). Within the mining of coal and lignite, the full-time employment rate in the EU-27 was 99.0%, the highest of any NACE division for which data are available, while among the remaining four NACE divisions that are included within the mining and quarrying sector, this proportion never fell lower than 94.6%.

The EU-27's mining and quarrying workforce was predominantly composed of men (86.2% of the total in 2007), 21.3 percentage points higher than the non-financial business economy average, and one of the highest proportions for all sectors.

In terms of its age profile, the EU-27's mining and quarrying sector is atypical. It had a considerably lower proportion of younger workers, as just 12.9% of those employed were aged less than 30. This was almost half the average share of this age group across the whole of the non-financial business economy (24.3%) and was also one of the lowest proportions recorded for all sectors. The relative importance of those aged 30 to 49 was, in contrast, very high – representing 63.2% of those employed within the mining and quarrying workforce – one of the highest ratios of all sectors, and 9.5 percentage points above the non-financial business economy average. The relative importance of those aged 50 or over in the mining and quarrying workforce (23.9% of the total) was more in line with the average for the non-financial business economy (which was 2 percentage points less). Although a more detailed analysis reveals that there was a particularly low share of those aged 50 or less working within the mining of coal and lignite sector (17.7%) – the third lowest share among NACE divisions – behind, only the manufacturing and service activities related to computers.

Expenditure, productivity and profitability

The mining and quarrying sector is generally characterised as a capital-intensive activity performed by large enterprises. This is particularly the case for projects that require exploration and test drilling, in advance of the considerable investment required to establish a new mine or off-shore drilling facility. Opencast (or surface) mines are generally cheaper than deep mines – although they may be rejected in the planning stage due to their effect on local landscapes. All forms of mining and quarrying incur environmental costs, which may relate to the disposal of waste, increased pollution, potential for ground subsidence, or changes to the local supply and quality of water.

The level of tangible investment made by the mining and quarrying sector in 2006 reached EUR 21.1 billion in the EU-27

, equivalent to 2.0% of all tangible investment made in the non-financial business economy. The investment rate shows the ratio between investment and value added: in 2006 this was 23.8% for the EU-27

's mining and quarrying sector, approximately 30% above the non-financial business economy average (18.4%).

As regards operating expenditure, the share of personnel costs was relatively low in the EU-27's mining and quarrying sector, at 13.3% in 2006 (compared with a non-financial business economy average of 16.1%). This was particularly the case for the extraction of crude petroleum and natural gas, where personnel costs accounted for 5.8% of total operating expenditure in 2006 – the second lowest figure among all NACE divisions in the non-financial business economy, behind the related downstream manufacturing activity of coke, refined petroleum products and nuclear fuel. In contrast, the mining and quarrying of non-energy producing materials was more labour-intensive.

The apparent labour productivity of the EU-27's mining and quarrying sector in 2006 was EUR 120.8 thousand per person employed. This was almost four times as high as the non-financial business economy average of EUR 43.5 thousand per person employed and was one of the highest levels of productivity for all structural business statistics sectors. The aggregate figure for the whole of the mining and quarrying sector was skewed by very high productivity levels for the extraction of crude petroleum and natural gas (EUR 370.0 thousand per person employed in 2005), while labour productivity for the mining of metal ores (EUR 109.7 thousand per person employed in 2006) was also considerably above the non-financial business economy average.

Average personnel costs within the EU-27

's mining and quarrying sector were EUR 31.3 thousand per employee in 2006, somewhat higher than the non-financial business economy average of EUR 28.8 thousand, but 7.1% lower than the average for all indus-

trial activities. Personnel costs per employee peaked at an estimated EUR 40.0 thousand per employee for the extraction of crude petroleum and natural gas in 2005, while the remaining three activities for which data are available (at the level of NACE divisions covered within the articles on mining and quarrying (no information available for the mining of uranium and thorium ores) all reported average personnel costs close to the non-financial business economy average.

The wage-adjusted labour productivity ratio combines the two previous ratios, and shows the extent to which value added per person employed covers average personnel costs per employee. In the EU-27's mining and quarrying sector in 2006, this ratio was 386.3%, one of the highest for all sectors. Of the five NACE divisions that make up the mining and quarrying sector, this ratio peaked at an estimated 900% for the extraction of crude petroleum and natural gas in 2005, while value added covered personnel costs by more than four times for the mining of metal ores in 2006. The mining of coal and lignite was the only activity to record a wage adjusted labour productivity ratio (115.0% in 2005) that was below the EU-27 average for the whole of the non-financial business economy (again no information available for the mining of uranium and thorium ores).

The **gross operating rate** (the relation between the **gross operating surplus** and **turnover**) is one measure of **profitability** ; it stood at 28.1% for the EU-27's mining and quarrying sector in 2006, more than twice non-financial business economy average (10.8%) – and one of the highest levels of profitability (using this measure) among any of the structural business statistics sectors. Profitability was particularly high for the mining of metal ores (48.9%), which recorded the highest gross operating rate among all of the NACE divisions within the non-financial business economy, while the rate for the extraction of crude petroleum and natural gas was third highest (31.2%).

Source: Eurostat (SBS)

Table 6: Mining and quarrying (NACE Section C). Main indicators, 2006

With a lack of natural resources (and therefore output), it is not surprising to find the EU-27

exports a relatively small amount of mining and quarrying products (CPA Section C). In 2007, these goods accounted for 1.7% of total industrial (CPA Sections C to E) exports, of which the majority (62.1%) were other mining and quarrying products (CPA Division 14).

The EU is highly dependent on non-member countries for its supplies of mining and quarrying products, and imports of these products accounted for 22.1% of all industrial (CPA Sections C to E) imports in 2007, when a trade deficit of EUR 273.8 billion was recorded. The overwhelming majority (83.6%) of the EU-27

's imports of mining and quarrying were of crude petroleum and natural gas (CPA Division 11).

The increasing reliance on imports continued a long-established trend, and the EU-27

trade deficit for mining and quarrying products more than doubled in the five years from 2002 to 2007. To put this deficit into perspective, it is several times higher than most of the other structural business statistics sectors. The reliance on external providers is also confirmed by analyzing the ratio of intra-EU to extra-EU imports for the 27 Member States, which stood at 23.7% for mining and quarrying products in 2007 – one of the only sectors where imports from non-member countries exceeded imports from other Member States.

Russia was the main origin of EU-27

mining and quarrying imports in 2007, accounting for almost one quarter (24.3%) of the total – a share that was almost twice that recorded for the second largest supplier, Norway (12.8%). The remaining countries that supplied mining and quarrying products to the EU-27

were largely dominated by oil-producing countries, such as Libya, Saudi Arabia or Iran, while Brazil, South Africa, Chile, Canada, Australia and Russia were among the most important suppliers of non-energy producing products.

In terms of world trade, Denmark was the only Member State where exports of mining and quarrying products were valued higher than imports, with a cover ratio of 345.2% in 2007; the next highest ratio being recorded for the United Kingdom (82.0%). The United Kingdom posted the highest level of mining and quarrying exports in 2007 (EUR 26.1 billion), which equated to 36.3% of the total exports made by the 27 Member States. Note that the relatively high external trade figures for Belgium and the Netherlands reflect the role played by main sea ports in these countries (in particular, the Amsterdam-Rotterdam-Antwerp (ARA) region), where bunker

facilities allow the temporary storage of mining and quarrying products before they are distributed across mainland Europe.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include [short-term statistics](#) , the [Labour force survey](#) and Eurostat's [COMEXT](#) database for external trade.

Context

The global mining and quarrying sector is characterised by a relatively small number of international enterprise groups, that operate across the continents – sometimes with only their head office in the EU or another developed economy. These large-scale producers are complemented by a large number of smaller enterprises, typically serving a local market in low-value, widely-available products, often for use in construction. The location of mining and quarrying activity generally reflects the spatial distribution of mineral deposits. However, there can be considerable cost differences between mines, for example, in relation to the depth at which deposits are found, or whether they are on land or at sea. Aside from geographical and geological cost differences, the decision of whether or not to (re-)open a mine may also depend, among others, on global, [commodity](#) prices, as well as regulations concerning the environmental impact of mining or the disposal of its waste.

The EU aims to become a low-carbon, energy-efficient economy in the coming years. The integrated energy and climate change policy laid out in December 2008 aims to cut [greenhouse gases](#) by 20%, reduce energy consumption by 20% through increased energy efficiency and to meet 20% of the EU's energy needs from [renewable sources](#) by 2020 – these goals will have implications on the way extractive activities operate.

Another important aspect in relation to this sector concerns the security of supply for downstream activities. Aside from well-publicised geopolitical disputes which have threatened the supply of crude petroleum or natural gas to European markets, there are also a large number of non-energy-related minerals, which are often essential for downstream manufacturing activities. There is no indigenous supply for many of these, with the extraction of construction materials being one of the few areas where the EU is largely self-sufficient.

Data from April 2012. Most recent data: Further Eurostat information, Main tables and Database

This article presents an overview of statistics for [European Union \(EU\)](#) mining and quarrying, covering [NACE Rev.2 SectionB](#). This activity concerns the extraction of:

- [fossil fuels](#) such as coal (Division05), crude petroleum and natural gas (Division06);
- ferrous and non-ferrous metal ores (Division07);
- construction materials (for example, stone and sand) and other industrial materials such as salt, phosphates and gemstones (Division08);
- it also includes mining support service activities (Division09).

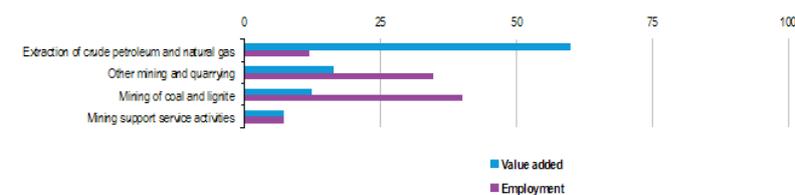

Note that the article only covers extractive activities, and not the downstream processing of fuel, nor the manufacture of non-metallic mineral products, both of which are classified under [manufacturing \(SectionC\)](#) , nor the [network supply of energy \(SectionD\)](#) .

Table 4b: Key indicators, mining and quarrying (NACE Section B), 2009- Source: Eurostat (sbs_na_ind_r2)

Main statistical findings

Structural profile

There were 20 thousand enterprises operating with mining and quarrying (Section B) as their main activity in the EU-27 in 2009. Together they employed 640 thousand persons, equivalent to 0.5% of all persons employed in the non-financial business economy (Sections B to J and L to N and Division 95), while they generated EUR72000 million of value added which was 1.3% of the non-financial business economy total.

The apparent labour productivity of the EU-27's mining and quarrying sector in 2009 was EUR112 thousand per person employed, almost 2.7 times as high as the non-financial business economy average of EUR41.6 thousand per person employed and the second highest ratio among the NACE sections that compose the non-financial business economy – behind electricity, gas, steam and air conditioning (EUR180 thousand per person employed). Despite high apparent labour productivity, average personnel costs within the EU-27's mining and

quarrying sector (EUR34.0 thousand per employee) were not particularly far above the average for the whole of the non-financial business economy (EUR30.0 thousand per employee). The [wage-adjusted labour productivity ratio](#) combines the two previous indicators and shows the extent to which value added per person employed covers average personnel costs per employee. Due to the high productivity and only slightly elevated average personnel costs the EU-27's mining and quarrying sector in 2009 had a wage-adjusted labour productivity ratio of 321% in 2009, which was also the second highest ratio across the NACE sections within the non-financial business economy, somewhat lower than the ratio for electricity, gas, steam and air conditioning (354%).

The [gross operating rate](#) (which measures the relation between the [gross operating surplus](#) and [turnover](#)) is one measure of profitability; it stood at 26.6% for the EU-27's mining and quarrying sector in 2009, which was 2.7 times as high as the non-financial business economy average (9.7%) – and the second highest level of profitability (using this measure) among any of the NACE sections within the non-financial business economy behind real estate activities (SectionL). It should be noted that this measure does not take account of depreciation or financial expenditure, which are typically higher in capital-intensive activities.

Sectoral analysis

Almost nine out of every ten enterprises within the EU-27's mining and quarrying sector extracted materials that were non-metallic and not fossil fuels and were thus classified in other mining and quarrying (Division08) – these enterprises were relatively small in size. The two largest subsectors in terms of employment were the mining of coal and lignite (Division05) and other mining and quarrying, each occupying more than one third of the mining and quarrying workforce. In output terms the relative importance of the extraction of fossil fuels was far greater, as the extraction of crude petroleum and natural gas (Division06) accounted for 59.8% of EU-27 sectoral value added, while a further 12.3% of sectoral added value was derived from the mining of coal and lignite. Mining support service activities (Division09) accounted for less than one tenth of the sector's value added and employment.

As can be seen from Figure1, the contribution of the various subsectors to the EU-27's mining and quarrying total varied considerably depending on whether value added or employment was used for analysis. The variation in the relative importance of the different subsectors was even more amplified for some of the derived indicators concerning personnel costs, labour productivity and profitability, as shown in Table2.

The high apparent labour productivity figure for the whole of the EU-27's mining and quarrying sector (EUR112 thousand per person employed in 2009) was pulled upwards by the subsector for the extraction of crude petroleum and natural gas where the apparent labour productivity reached EUR569 thousand per person employed, more than three times as high as for any other NACE division within the whole of the non-financial business economy. Mining support service activities also recorded relatively high apparent labour productivity (EUR115 thousand per person employed), while the mining of coal and lignite had the lowest apparent labour productivity among the mining and quarrying NACE divisions (information for the mining of metal ores (Division07) is not available), with a ratio (EUR34.0 thousand per person employed) that was considerably lower than the non-financial business economy average (EUR41.6 thousand per person employed).

At the NACE division level, personnel costs per employee in the EU-27 peaked at EUR65.0 thousand per employee for the extraction of crude petroleum and natural gas in 2009, ahead of mining support service activities (EUR50.1 thousand per employee). The other mining and quarrying subsector reported average personnel costs (EUR31.0 thousand per employee) that were almost the same as for the whole of the non-financial business economy, some EUR1.0 thousand per employee higher. A somewhat lower average personnel cost was recorded for the mining of coal and lignite (EUR25.1 thousand per employee), in part reflecting the geographical distribution of this activity that is concentrated in eastern Europe.

In three out of the four mining and quarrying NACE divisions for which data are available the EU-27 wage-adjusted labour productivity ratio exceeded the non-financial business economy average (138.8%). This ratio ranged from 137.3% for the mining of coal and lignite to 875.6% for the extraction of crude petroleum and natural gas in 2009.

For the gross operating rate, data is available for four of the five mining and quarrying NACE divisions. For the EU-27 this variable was consistently higher across all four subsectors in 2009 when compared with the average operating profit rate for the whole of the non-financial business economy (9.7%), as profitability (using this measure) ranged from 15.5% for other mining and quarrying to 30.8% for the extraction of crude petroleum

and natural gas.

Country analysis

With oil and gas fields off its east coast it is unsurprising that the United Kingdom recorded the highest share (35.6%) of EU-27 value added within the mining and quarrying sector in 2009. Denmark and the Netherlands (predominantly natural gas), as well as Germany and Poland (predominantly coal and lignite) were also relatively important producers within the EU in value added terms. The Polish mining and quarrying workforce of 190.0 thousand persons was equivalent to almost one third (29.7%) of the EU-27 total, and was followed by Romania (12.2%) and Germany (11.4%). The five largest Member States in the mining and quarrying sector accounted for a larger share of EU-27 value added and employment than was typical for the non-financial business economy as a whole (see Figure 3), underlining the geographical concentration and specialisation that occurs within this sector.

The relative importance of the mining and quarrying sector across the Member States tended to be highest among those countries specialised in the extraction of fossil fuels: in value added terms Denmark, the Netherlands and the United Kingdom were most specialised Member States for mining and quarrying in 2009, along with Norway. These figures were closely linked to the geological distribution of fossil fuel deposits which were scarce or non-existent in many of the Member States. Bulgaria was specialised in the extraction of metal ores, while Latvia and Cyprus recorded some of the highest specialisation ratios with respect to other mining and quarrying. The United Kingdom, Romania and the Netherlands were the most specialised in mining support service activities.

These various specialisations are reflected in the derived indicators shown in Table 4b. For example, Member States with a high degree of specialisation in the extraction of crude petroleum and natural gas recorded high apparent labour productivity for mining and quarrying as a whole, as can be seen for Denmark the Netherlands and the United Kingdom.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

The location of mining and quarrying generally reflects the spatial distribution of mineral deposits. However, there can be considerable cost differences between mines, for example, in relation to the depth at which deposits are found, or whether they are on land or at sea. Aside from geographical and geological cost differences, the decision of whether or not to (re-)open a mine may also depend, among others, on global, commodity prices, employment practices, as well as regulations concerning the environmental impact of mining or the disposal of its waste. Opencast (or surface) mines and quarries are generally cheaper than deep mines – although they may be rejected in the planning stage due to their effect on local landscapes. All forms of mining and quarrying incur environmental costs, which may relate to the disposal of waste, increased pollution, potential for ground subsidence, or changes to the local supply and quality of water.

The mining and quarrying sector is characterised as a capital-intensive activity. This is particularly the case for projects that require exploration and test drilling in advance of the considerable investment required to establish a new mine or off-shore drilling facility. As such, the global mining and quarrying sector is characterised by a relatively small number of international enterprise groups that operate across the continents – some with extraction and/or support service operations in the EU. These large-scale producers are particularly common in the extraction of fossil fuels. The vast majority of hard coal and lignite that is extracted or imported into the EU is consumed as a transformation input, mostly used in conventional thermal power stations or in coke oven plants. Over several decades the EU's coal mining activity has been in decline due to competition from

coal imports and the substitution of other fuels to produce electricity, the latter stimulated in part by efforts to reduce emissions. Crude oil is essentially a transformation input, used in refineries. Despite increased prices in recent years stimulating exploration and increasing the economic viability of existing fields, extraction of oil and gas by EU Member States started to decline around the turn of the millennium.

Many of the products resulting from the activity of this sector are traded globally and prices are established for global markets. One of the most closely followed prices is the price of crude oil, which is not only of interest for this sector itself, but also for the many downstream activities that are intensive users of energy as well as the chemicals sector that uses petroleum as a raw material.

The extraction of construction materials is dominated by a large number of smaller enterprises, typically serving a local market in low-value, widely-available products. Whilst the EU is largely self-sufficient in the extraction of construction materials, there are a large number of other minerals that are essential for downstream manufacturing activities for which there is no indigenous supply within the EU; for example the EU has high net imports of metallic minerals. Other industrial minerals are often further processed in downstream industrial sectors, for example, in the manufacture of glass, concrete and basic or agricultural chemicals. Minerals are also used in industrial processes and precious and semi-precious stones and metals are used in jewellery and for some industrial processes.

Policies related to energy and to climate change are particularly important for many parts of the mining and quarrying sector. The EU aims to become a low-carbon, energy-efficient economy in the coming decades. The integrated energy and climate change policy laid out in December 2008 aims to cut [greenhouse gases](#) by 20%, reduce energy consumption by 20% through increased energy efficiency and to meet 20% of the EU's energy needs from [renewable sources](#) by 2020 – these goals will have implications on the way extractive activities operate. In a Communication in November 2010 the European Commission presented its [Energy 2020](#) strategy for competitive, sustainable and secure energy – see also the article on the [electricity, gas, steam and air conditioning supply sector](#) .

Main statistical findings

Structural profile

Enterprises operating with mining of coal and lignite (Division05) as their main activity employed 257 thousand persons in the EU-27 in 2009, equivalent to 0.2% of all persons employed in the [non-financial business economy](#) (Sections B to J and L to N and Division 95) and 40% of persons working in mining and quarrying. These enterprises generated EUR8843 million of value added which was also 0.2% of the non-financial business economy total, or some 12% of the added value for the whole of mining and quarrying.

The [apparent labour productivity](#) of the EU-27's mining of coal and lignite sector in 2009 was EUR34.0 thousand per person employed, below the non-financial business economy average of EUR41.6 thousand per person employed and the much higher mining and quarrying average of EUR112 thousand per person employed. In line with this low apparent labour productivity, [average personnel costs](#) within the EU-27's mining of coal and lignite sector were also below average: at EUR25.1 thousand per employee compared with an average of EUR30.0 thousand per employee for the whole of the non-financial business economy. The [wage-adjusted labour productivity ratio](#) combines the two previous indicators and shows the extent to which value added per person employed covers average personnel costs per employee. Due to relatively low productivity and only slightly inferior average personnel costs (when compared with the non-financial business economy average), the EU-27's mining of coal and lignite sector had a wage-adjusted labour productivity ratio of 137.3% in 2009, marginally lower than the non-financial business economy average (138.8%).

The [gross operating rate](#) (the relation between [gross operating surplus](#) and [turnover](#)) is one measure of profitability; it stood at 17.2% for the EU-27's mining of coal and lignite sector in 2009, a little under twice as high as the non-financial business economy average (9.7%). It should be noted that this measure does not take account of depreciation or financial expenditure, which are typically higher in capital-intensive activities.

Sectoral analysis

The mining of coal and lignite sector is broken down in the NACE classification into two subsectors at the NACE group level of detail. The mining of hard coal (Group05.1) was the largest of these two subsectors in terms of employment and value added in the EU-27: it generated 73.6% of sectoral value added and occupied 75.0% of the workforce. The mining of lignite (Group05.2) made up the remainder of the mining of coal and lignite sector. As such, the contribution of the two subsectors to the mining of coal and lignite total was similar

in terms of their shares in both sectoral value added and employment (as shown in Figure1).

This apparent similarity was not reflected across all indicators, and differences between the two subsectors were particularly pronounced in relation to labour costs. At the NACE group level, EU-27 average personnel costs per employee were EUR26.7 thousand per employee for hard coal mining in 2009 while they were just EUR 20.4 thousand per employee for lignite mining. The low apparent labour productivity figure for the whole of the mining of coal and lignite sector was common to both subsectors, with the mining of lignite recording a value of EUR 36 thousand per person employed, just EUR2 thousand higher than for hard coal mining. The combination of particularly low average personnel costs and slightly higher apparent labour productivity resulted in a high wage-adjusted labour productivity ratio in lignite mining, reaching 179.1%, well above the non-financial business economy average (138.8%). In contrast, for hard coal mining this ratio was 126.7%. The relatively low average personnel costs for lignite mining also helped to raise the gross operating rate in this subsector to 24.6% in 2009, compared with 14.0% for hard coal mining; the latter was, nevertheless, still above the non-financial business economy average (9.7%).

Country analysis

At least nine Member States had no enterprises (and therefore no output or employment) in the mining of coal and lignite sector in 2009 – see Tables 4a and 4b. Poland recorded the highest share (47.5%) of EU-27 value added within the mining of coal and lignite sector in 2009, while Germany and the Czech Republic were also relatively important producers in value added terms; the combined output of these three Member States was equivalent to 84.5% of the EU-27 total output in this sector. Poland also had the largest workforce for the mining of coal and lignite, 142.4 thousand persons, over half the EU-27 total. The relatively high share of a small number of Member States in the EU-27's value added and employment in the mining of coal and lignite sector underlined the geographical concentration and specialisation of this sector.

Poland had the highest level of value added for both of the subsectors, accounting for more than half of the EU-27's value added in hard coal mining and just under one quarter of the total for lignite mining. Unsurprisingly, Poland was also the most specialised Member State (in value added terms) in hard coal mining (followed by the United Kingdom), while Bulgaria and Poland were the most specialised Member States for lignite mining.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the mining of coal and lignite sector in the EU, covering NACE Rev. 2 Division 05. The extraction of solid mineral fuels such as coal and lignite includes underground or open-cast mining and includes operations (for example, grading, cleaning, compressing and other steps necessary for transportation and so on) leading to a marketable product.

This NACE division is composed of two groups:

- the mining of hard coal (Group 05.1);
- the mining of lignite also known as brown coal (Group 05.2).

This article does not cover peat-digging (which is classified to Division 08, [other mining and quarrying](#)), coking or the manufacture of briquettes (Division 19, the [manufacture of coke and refined petroleum products](#)) or services incidental to coal or lignite mining (Division 09, [mining support services](#)).

Source: Eurostat (online data code: sbs_na_ind_r2)

Table 3b: Key indicators, mining of metal ores (NACE Division07), 2009- Source: Eurostat (sbs_na_ind_r2)

Main statistical findings

There were approximately 240 enterprises operating with mining of metal ores (Division07) as their main activity in the EU-27 in 2009. The sector is composed of the mining of iron ores (Group07.1) and the mining of non-ferrous metal ores (Group07.2). Data availability for iron ore mining is relatively limited and the analysis presented in this structural profile focuses on the mining of non-ferrous metal ores.

Around 38.5 thousand persons were employed in the mining of non-ferrous metal ores in the EU-27 in 2009, equivalent to 6.0% of all persons employed in mining and quarrying (SectionB). They generated EUR2830 million of value added which was 3.9% of the mining and quarrying total. The **apparent labour productivity** of the EU-27's mining of non-ferrous metal ores subsector in 2009 was EUR74 thousand per person employed, well above the **non-financial business economy** average of EUR41.6 thousand per person employed and the mining and quarrying average of EUR112 thousand per person employed. Despite this high apparent labour productivity the **average personnel costs** within the EU-27's mining of non-ferrous metal ores subsector were not high,

averaging EUR30.4 thousand per employee which was in line with the EUR30.0 thousand per employee average for the non-financial business economy. Apparent labour productivity was equivalent to 242.0% of the average personnel costs (this is the [wage-adjusted labour productivity ratio](#)) in the EU-27's mining of non-ferrous metal ores subsector in 2009, a level that was well above the non-financial business economy average (138.8%) but below the mining and quarrying average (321.4%). The [gross operating rate](#) (which is the gross operating surplus in relation to turnover) stood at 34.1% for the EU-27's mining of non-ferrous metal ores subsector in 2009, around three and a half times as high as the non-financial business economy average (9.7%) and above the 26.6% average for the whole of the mining and quarrying sector.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the mining of metal ores sector in the EU, covering NACE Rev.2 Division07. This division includes mining for metallic minerals (ores), performed through underground or open-cast extraction, seabed mining and so on. Also included are ore dressing and operations such as crushing, grinding, washing, drying, sintering, calcining (thermal treatment) or leaching ore, gravity separation or flotation operations.

Non-ferrous metal ores include uranium and thorium ores as well as other non-ferrous metal ores such as aluminium (bauxite), copper, lead, zinc, tin, manganese, chrome, nickel, cobalt, molybdenum, tantalum, vanadium and precious metals (for example, gold, silver, platinum).

This NACE division is composed of two groups:

- the mining of iron ores (Group07.1);
- and the mining of non-ferrous metal ores (Group07.2).

Excluded are: the extraction and preparation of pyrites and pyrrhotite (Division 08, [other mining and quarrying](#)), the roasting of iron pyrites and enrichment of uranium and thorium ores (Division 20, [chemicals manufacturing](#)), the production of aluminium oxide, mattes of copper or of nickel, smelting and refining of uranium, and the operation of blast furnaces (Division24, [basic metals manufacturing](#)).

Main statistical findings

Structural profile

There were 1.3 thousand enterprises operating with mining support services (Division09) as their main activity in the EU-27 in 2009 and together they employed 45 thousand persons, equivalent to 7.0% of all persons employed in mining and quarrying (Section B). The value added generated in this sector reached EUR 5156 million which was 0.1% of the non-financial business economy (Sections B to J and L to N and Division95) total and 7.2% of the mining and quarrying total.

Average personnel costs within the EU-27's mining support services sector were relatively high, reaching EUR 50.1 thousand per employee in 2009 compared with EUR 30.0 thousand per employee on average across the whole of the non-financial business economy and EUR 34.0 thousand per employee for mining and quarrying. The apparent labour productivity of the mining support services sector was also high, EUR 115 thousand per person employed, well above the non-financial business economy average of EUR 41.6 thousand per person employed and slightly higher than the mining and quarrying average (EUR 112 thousand per person employed).

The resulting wage-adjusted labour productivity ratio shows that in 2009 apparent labour productivity was equivalent to 228.4% of the average personnel costs in the EU-27's mining support services sector. This was higher than the non-financial business economy average (138.8%), but lower than the mining and quarrying average (321.4%), as the latter was pulled up by the extraction of crude petroleum and natural gas (Division06). A similar situation can be observed for the gross operating rate, which was 22.8% for the EU-27's mining support services sector in 2009. This measure of operating profitability (relating the gross operating surplus and turnover) was more than twice as high in the mining support services sector in 2009 than it was, on average, in the non-financial business economy (9.7%), but was lower than the mining and quarrying average (26.6%) which was again elevated by the extraction of crude petroleum and natural gas (30.8%).

Sectoral analysis

The mining support services sector is split between two subsectors, depending whether the support services are provided for the extraction of petroleum and natural gas (Group09.1) or for other types of mining and quarrying (Group09.2).

Support activities for petroleum and natural gas extraction dominated the sector in the EU-27, accounting

for 68.1% of the enterprise population in 2009, contributing 86.9% of sectoral employment and generating more than 95% of the sectoral turnover and value added. As a result, the support activities for petroleum and natural gas extraction recorded higher apparent labour productivity than the support activities for other mining and quarrying. This relatively high level of apparent labour productivity for support activities for petroleum and natural gas extraction (EUR129 thousand per person employed) was above the mining and quarrying average, as was this subsector's average personnel costs (EUR55.2 thousand per employee) – see Table2b. In contrast, although this subsector's wage-adjusted labour productivity ratio (233.1%) and gross operating rate (23.1%) were also above the non-financial business economy averages they were both below mining and quarrying averages.

Support activities for other mining and quarrying recorded relatively low apparent labour productivity and average personnel costs in the EU-27 in 2009, both less than half the non-financial business economy average. In contrast, this subsector's wage-adjusted labour productivity ratio (133.6%) was only slightly below the non-financial business economy average and its gross operating rate (10.5%) was slightly above the non-financial business economy average.

Country analysis

More than half (57.0%) of the value added within the EU-27's mining support services sector in 2009 was generated in the United Kingdom; this reflected the importance of the extraction of crude petroleum and natural gas (which is the main client of the related support activities) in the United Kingdom. Poland had the highest value added in the subsector concerning support activities for other mining and quarrying, with a 29.2% share of EU-27 value added. Unsurprisingly the United Kingdom was the most specialised Member State in the mining support services sector, generating 0.3% of non-financial business economy value added in this activity, narrowly ahead of Romania and the Netherlands (also 0.3%); for comparison, this share reached 2.7% in Norway.

From Table4b it can be seen that the Netherlands had by far the highest wage-adjusted labour productivity ratio (309.7%) among the Member States for which data are available, followed by Spain and the United Kingdom.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the mining support service activities sector in the EU, covering NACE Rev.2 Division09. This division includes specialised support services incidental to mining provided on a fee or contract basis. It includes exploration services through traditional prospecting methods such as taking core samples and making geological observations as well as drilling, test-drilling or re-drilling for oil wells, metallic and non-metallic minerals. Other typical services cover building oil and gas well foundations, cementing oil and gas well casings, cleaning, bailing and swabbing oil and gas wells, draining and pumping mines, overburden removal services at mines, and so on. Also included are oil and gas field fire fighting services.

This NACE division is composed of two groups:

- support activities for petroleum and natural gas mining (Group09.1);
- support activities for other mining and quarrying (Group09.9).

Excluded are service activities performed by operators of oil or gas fields or operating mines or quarries on a contract or fee basis (Divisions05 to08, mining and quarrying activities), specialised repair of mining machinery

(Division33, [repair and installation of machinery and equipment](#)) and geophysical, geologic and seismic surveying (Division71, [architectural and engineering activities](#)).

Table 4b: Key indicators, motion picture, video and television programme production, sound recording and music publishing activities (NACE Division 59), 2009 - Source: Eurostat (sbs_na_1a_se_r2)

Main statistical findings

Structural profile

The motion picture and sound recording activities (Division 59) sector comprised 95 thousand enterprises in the EU-27 in 2009. Together they employed 413 thousand persons, equivalent to 0.3% of all persons employed in the non-financial business economy (Sections B to J and L to N and Division 95) and 7.2% of persons in information and communication services (Section J). They generated EUR 20622 million of value added which was 0.4% of the non-financial business economy total and 4.3% of the information and communication services total.

The apparent labour productivity of the EU-27's motion picture and sound recording activities sector in 2009 was EUR 50.0 thousand per person employed, above the non-financial business economy average of EUR 41.6 thousand per person employed, but well below the information and communication services average of EUR 83 thousand per person employed. Average personnel costs within the EU-27's motion picture and sound recording activities sector were, at EUR 40 thousand per employee, higher than the EUR 30.0 thousand per employee average for the non-financial business economy, but again were below the information and communication services average (EUR 48.6 thousand per employee). The wage-adjusted labour productivity ratio combines these two previous indicators, showing the extent to which value added per person employed covers average personnel costs per employee. This ratio stood at 124.7% for the EU-27's motion picture and sound recording activities in 2009, which was below both the non-financial business economy average (138.8%) and the information and communication services average (171.2%).

The gross operating rate (the relation between the gross operating surplus and turnover) is a measure of operating profitability; it stood at 11.3% for the EU-27's motion picture and sound recording activities sector in 2009, somewhat higher than the non-financial business economy average of 9.7%, but well below the information and communication services average (20.9%). Indeed, this was the lowest level of profitability (using this measure) among the five NACE divisions for which data are available within information and communication services.

Sectoral analysis

Motion picture and sound recording activities can be split into two constituent parts. Of these, by far the larger in the EU-27 was motion picture, video and television programme activities (Group 59.1), which accounted for just over 90% of sectoral value added and employment in 2009. The relative importance of sound recording

and music publishing activities (Group59.2) was somewhat larger in relation to the number of enterprises, with 18900 enterprises representing almost 20% of the sectoral total.

The difference in the level of apparent labour productivity between the two subsectors that make-up the motion picture and sound recording activities sector was fairly small. The larger motion picture, video and television programme activity subsector had EU-27 apparent labour productivity of EUR50 thousand per person employed in 2009, while productivity for the sound recording and music publishing activities subsector was some EUR8 thousand per person employed higher in 2008; note that the apparent labour productivity of many activities fell between 2008 and 2009 as a result of the financial and economic crisis.

EU-27 personnel costs per employee peaked at EUR40 thousand per employee for the motion picture, video and television programme activities subsector in 2009, which was EUR5.2 thousand per employee more than for the sound recording and music publishing activities subsector in 2008.

This combination of higher apparent labour productivity and lower average personnel costs meant that the sound recording and music publishing activities subsector had a much higher wage-adjusted labour productivity ratio (157.0% in 2008) than the non-financial business economy (138.8%), the motion picture and sound recording activities sector as a whole (124.7%), or the motion picture, video and television programme activities subsector (120.0%); the latter three figures are all for 2009.

For the gross operating rate a similar picture was observed, as the EU-27 gross operating surplus for the sound recording and music publishing activities subsector was equivalent to 14.7% of turnover in 2009. This was well above the corresponding profitability measures that were recorded for the motion picture and sound recording activities sector (11.3%), the smaller subsector of motion picture, video and television programme activities (10.9%), or the non-financial business economy average (9.7%).

Country analysis

France recorded the highest share (29.9%) of EU-27 value added within the motion picture and sound recording activities sector in 2009, at EUR6165 million; this was the highest share of EU-27 value added for France in any of the non-financial business economy NACE divisions (with data available) in 2009. The French value added in this sector was almost twice as high as the level of value added in Germany – the second highest contributor to EU-27 sectoral value added (15.4%) – while the United Kingdom was the only other Member State to report a double-digit share of the EU-27 total (13.2%). Other measures of size, suggest that the motion picture and sound recording activities sector was relatively more important in the United Kingdom than reflected by value added, as it accounted for 28.1% of EU-27 employment in 2009 and a 16.5% share of the total number of enterprises within the EU-27's motion picture and sound recording activities sector; in both of these cases the United Kingdom reported the highest share of the EU-27 total among the Member States. A more detailed breakdown shows that the relative weight of France was boosted by its high level of added value for the motion picture, video and television programme activities subsector; 31.1% of the EU-27 total in 2009. Germany accounted for the highest share (25.6%) of EU-27 value added for the sound recording and music publishing activities subsector.

The contribution of the motion picture and sound recording activities sector to non-financial business economy value added rose to 1.1% in Hungary, which was considerably higher than in any of the other Member States, the second most specialised Member State was France (where the motion picture and sound recording activities sector provided 0.8% of non-financial business economy value added).

Hungary also reported the highest wage-adjusted labour productivity ratio for motion picture and sound recording activities in 2009, at 639.7%; this was almost four times as high as the average wage-adjusted labour productivity ratio for Hungary across the whole of the non-financial business economy. Furthermore, Hungary recorded the highest level of gross operating profitability, with its gross operating rate reaching 36.0% in 2009 for motion picture and sound recording activities; this was 4.3 times as high as the Hungarian average for the whole of the non-financial business economy. A gross operating rate of 22.1% was recorded for motion picture and sound recording activities in France, which was 3.4 times as high as the French average for the whole of the non-financial business economy.

At the other end of the range, the United Kingdom was the only Member State to record a wage-adjusted labour productivity ratio below 100% in this sector, providing further evidence that the value added generated by motion picture and sound recording activities in this Member State was comparatively low in both 2008

and 2009 when compared with other indicators (such as employment) that suggested this sector was relatively developed in the United Kingdom. The relatively low level of value added in the United Kingdom resulted in a negative gross operating surplus, which in turn fed through into a gross operating rate of -11.1% for motion picture and sound recording activities – the only negative rate among the Member States.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the motion picture and sound recording activities sector in the EU, as covered by NACE Rev.2 Division59. This division includes activities related to theatrical and non-theatrical motion pictures whether on film, video tape or disc for direct projection in theatres or for broadcasting on television. These activities concern various stages from production, through post-production and distribution to projection. Buying and selling of motion picture or other film production distribution rights is also included. Post-production activities include activities such as editing, film/tape transfers, titling, subtitling, credits, closed captioning, computer-produced graphics, animation and special effects, developing and processing motion picture film and activities of motion picture film laboratories.

This division also includes sound recording activities, in other words, the production of original sound master recordings, releasing, promoting and distributing them, the publishing of music, as well as sound recording service activities in a studio or elsewhere. This activity also includes music publishing, in other words, activities of acquiring and registering copyrights for musical compositions, promoting, authorising and using these compositions in recordings, radio, television, motion pictures, live performances, print and other media. Units engaged in these activities may own the copyright or act as an administrator of the music copyrights on behalf of the copyright owners. Publishing of music and sheet books is also included.

This NACE division is composed of two groups:

- motion picture, video and television programme activities (Group59.1);
- sound recording and music publishing activities (Group59.2).

Excluded are film duplicating (except reproduction of motion picture film for theatrical distribution) as well as audio and video tape, CD or DVD reproduction from master copies (Division18, part of [printing and reproduction of recorded media](#)), the wholesaling, retailing or renting of video tapes, discs and so on (Divisions46, 47 and 77, [wholesale trade](#) , [retail trade](#) and [renting and leasing of goods](#)), television broadcasting and the creation of complete television channel programmes (Division60, part of [programming and broadcasting activities](#)), film processing other than for the motion picture industry (Division74, part of [other professional, scientific and technical activities](#)).

Motor and fuel retail trade statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article introduces a [set of statistical articles](#) which analyse the structure, development and characteristics of the economic activities in the motor trades sector in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), this sector covers NACE Division 50, which is the [wholesale](#), retail sale and repair of motor vehicles and motorcycles, as well as the retailing of automotive fuels and lubricants. Its activities are treated in more depth in two further articles:

- [Car and motorcycle trade](#), corresponding to NACE Groups 50.1-50.4.
- [The retail of fuel and lubricating and cooling products](#), corresponding to NACE Group 50.5.

Table 5: Motor trades (NACE Division 50). Main indicators, 2006 (1)

Main statistical findings

Structural profile

There were 809.0 thousand enterprises active in the EU-27's motor trades (NACE Division 50) sector in 2006, employing 4.2 million persons, which represented 3.3% of the non-financial business economy (NACE Sections C to I and K) workforce. The proportion of the persons employed that were paid employees (as opposed to working proprietors or unpaid family workers) in the EU-27's motor trades sector was 82.7%, close to the 82.2% registered for distributive trades (NACE Section G) as a whole, but well below the 86.5% average for the whole of the non-financial business economy. This workforce generated EUR 1.3 trillion of turnover, from which there

was EUR 161.8 billion of [value added](#) (the equivalent of 2.9% of the non-financial business economy total).

The retail sale of automotive fuel (NACE Group 50.5, see [Fuel retail and service station statistics](#)) accounted for 8.6% of the value added in this sector and 13.4% of turnover, while it contributed 11.8% of the labour force. The high turnover share reflects the purely [distributive](#) nature of this activity, whereas motor vehicles and motorcycles distribution (NACE Groups 50.1 to 50.4, see [Fuel retail and service station statistics](#)) is a mixture of wholesale and retail trade, as well as repair, maintenance and other services activities.

Among the Member States with available data⁸⁵, Germany and the United Kingdom recorded the highest levels of value added and employment in 2006. Together they contributed 31.8% of EU-27 employment and 45.4% of EU-27 value added. However, in terms of relative shares in the value added of the non-financial business economy⁸⁶, Latvia had the largest motor trades' sector (5.0%), followed by Greece (4.0%) and Lithuania (3.9%). In employment terms⁸⁷, Lithuania and Greece were joined by Cyprus (2005) as the most specialised.

Regional specialisation can be seen in the map presented – based on the employment share of this sector in the whole non-financial business economy. Motor trades share of non-financial business economy employment was highest (at the level of detail shown in the map) in Molise (Italy), reaching 9.3% of the non-financial business economy workforce. The next six most specialised regions, all with 6.0% or more of their non-financial business economy workforce in motor trades, included the two regions of Brandenburg (Südwest and Nordost) in Germany and the French islands of Réunion, Guadeloupe and Martinique, as well as Guyane. The least specialised region was inner London (United Kingdom), where motor trades contributed just 0.8% of the non-financial business economy workforce, around half the share of the three next least specialised regions – which were all in Slovakia.

[Short-term statistics](#) provide a picture of the development of the motor trades sector in the EU-27 over approximately ten years, in terms of turnover and employment indices. The annual growth rate for the EU-27's motor trades turnover index (in current prices) was never lower than 1.8% between 1998 and 2007, and reached a high of 5.7% in 2004 and 2006. From 2000 to 2007 the annual average turnover growth rate in motor trades was 4.8%, slightly below the non-financial services (NACE Sections G to I and Divisions 72 and 74) average of 5.3%, due mainly to slower growth in motor trades in the years 2005 to 2007. The [index of employment](#) for motor trades was stable or increased each year from 1998 to 2007. Motor trades averaged employment growth of 1.2% per year during the nine years from 1998 to 2007, only just over half the 2.3% average for non-financial services.

An analysis by enterprise size-classes shows that [small and medium-sized enterprises](#) (with less than 250 persons employed, namely SMEs) generated close to four fifths (78.8%) of the EU-27's motor trades value added and employed close to nine tenths (88.2%) of the workforce in 2006. [Micro](#) and small motor trades enterprises (with between 1 and 49 persons employed) were of particular note, as these enterprises contributed close to three fifths (57.8%) of sectoral value added in the EU-27, a proportion that was only exceeded in construction and real estate activities when considering all of the non-financial business economy NACE divisions.

Focus on motor trade products

A five-yearly analysis of turnover by product permits a more detailed analysis of motor trades, in particular distinguishing wholesale and retail motor trades, as well as other types of services. Average figures are presented on the basis of information for the 13 Member States for which data are available⁸⁸. Retail sales accounted for a larger proportion of turnover than wholesale sales for motor vehicles, for parts and accessories, and for motorcycles. Care should be taken with the data related to sales of motor vehicles on a fee or contract basis: this was just over 5% of the total turnover of motor trades products, but nearly all of this was recorded in Belgium suggesting a particular retail model for motor vehicles distribution in Belgium – when excluding Belgium from the average, the share of this type of sale fell to less than 1%.

⁸⁵Bulgaria and Poland, 2005; Malta, not available.

⁸⁶Bulgaria, Cyprus, Poland and Romania, 2005; Malta and the Netherlands, not available.

⁸⁷Bulgaria, Cyprus, the Netherlands, Poland and Romania, 2005; Malta, not available.

⁸⁸Belgium, Germany, Estonia, Ireland, Spain, France, Cyprus, Latvia, Lithuania, Austria, Portugal, Finland and Sweden.

Employment characteristics

The sector showed atypical employment characteristics compared with both the other distributive trades activities and with the non-financial business economy as a whole, particularly concerning the importance of younger workers, and to a lesser extent the share of male workers.

According to Labour Force Survey data for motor trades in 2007, men represented 81.9% of the EU-27's workforce, 17.0 points above the corresponding share for the non-financial business economy average. The high proportion of men that were employed in the motor trades sector was apparent across all the Member States; the lowest share of 74.7% was recorded for Slovenia.

Turning to an analysis by age, those aged between 15 and 29 were relatively over represented in motor trades compared with the non-financial business economy average in 2007: in motor trades 29.0% of the EU-27's workforce was in this age bracket compared with 24.3% for the non-financial business economy as a whole. As such, the motor trades sector had the third highest share of younger workers across all of the NACE divisions in the non-financial business economy, and the third lowest (50.4%) share of workers aged 30 to 49.

Slightly more than nine tenths of all persons employed in the EU-27's motor trade sector in 2007 worked full-time (90.5%), above the non-financial business economy average (85.7%). Only in six of the Member States was the incidence of full-time work lower in motor trades than the non-financial business economy average, and in all of these cases the difference was less than 1.5 percentage points.

Expenditure, productivity and profitability

The EU-27's motor trades sector recorded **tangible investment** to the value of EUR 22.7 billion in 2006, equivalent to 2.2% of the tangible investment made in the whole of the non-financial business economy, less than this sector's share of value added. The **investment rate** (the percentage ratio of investment to value added) was 14.0% for the motor trades sector, 4.3 percentage points below the average for the non-financial business economy.

In 2006, the share of purchases of goods and services in total operating expenditure for motor trades in the EU-27 was 92.8%, and the corresponding share of personnel costs 7.2%. This high share for goods and services reflects the high purchases and turnover associated with all distributive trades (NACE Section G) activities, which generally buy and resell products without transformation. To put this in perspective, the share of **personnel costs** in the motor trades sector was less than half the average for the non-financial business economy as a whole (16.1%), and was the fourth lowest share among all NACE divisions in the non-financial business economy with 2005 or 2006 data available. The retail sale of automotive fuel subsector recorded a particularly low share of personnel costs, just 4.0%, while the corresponding share for the motor vehicles and motorcycles distribution subsector was 7.7%.

Apparent **labour productivity** in the EU-27's motor trades was EUR 38.1 thousand per person employed and average personnel costs were EUR 25.6 thousand per employee. The level of both of these indicators was more than 10% below the non-financial business economy average. When combined to produce **wage-adjusted labour productivity**, however, the ratio for motor trades (148.8%) was only slightly below that for the non-financial business economy as a whole (151.1%). The two subsectors showed quite different values for these three indicators, with the retail sale of automotive fuel recording lower apparent labour productivity, much lower average personnel costs, and therefore a higher wage-adjusted labour productivity.

The **gross operating rate** (the ratio of gross **operating surplus** to turnover) in the EU-27's motor trades sector was 5.4% in 2006, half the average for the non-financial business economy. As such, the motor trades sector recorded the fourth lowest rate among all the non-financial business economy NACE divisions. The relatively high turnover inherent in the retail sale of automotive fuel subsector resulted in a particularly low gross operating rate of just 4.0% for this subsector, compared with a rate of 5.6% for the motor vehicles and motorcycles distribution subsector.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include [short-term statistics \(STS\)](#) and the [Labour force survey \(LFS\)](#) .

Context

The activities within this sector are very different in terms of the frequency of purchase of the goods and services offered. In contrast to the retail of automotive fuel, the purchase of motor vehicles is usually the result of a long-term process, the collection of information and comparison between different vehicles and different suppliers. However, retailing and repair of motor vehicles are to some extent substitutes, in that the purchase of a replacement vehicle may often be postponed, particularly in times of economic hardship.

Table 4b: Key indicators, wholesale and retail trade and repair of motor vehicles and motorcycles (NACE Division45), 2009 - Source: Eurostat (sbs_na_dt_r2)

Main statistical findings

Structural profile

There were 765 thousand enterprises operating with motor trades (Division45) as their main activity in the EU-27 in 2009. Together they employed 4.0 million persons, equivalent to 3.0% of all persons employed in the non-financial business economy (Sections B to J and L to N and Division95) and 12.0% of the distributive trades (Section G) workforce. They generated EUR127658 million of value added which was 2.3% of the non-financial business economy total and 11.5% of the distributive trades total.

The apparent labour productivity of the EU-27's motor trades sector in 2009 was EUR32 thousand per person employed, around one quarter lower than the non-financial business economy average (EUR41.6 thousand per person employed) but broadly in line with the distributive trades average (EUR33 thousand per person employed). This sector's average personnel costs were EUR27.3 thousand per employee, again below the non-financial business economy average (EUR30.0 thousand per employee) but in this case above the average for distributive trades (EUR25.0 thousand per employee). Compared with the distributive trades average, the higher than average personnel costs and slightly lower apparent labour productivity for the EU-27's motor trades sector in 2009 resulted in a wage-adjusted labour productivity ratio that was relatively low, 117.4% — the distributive trades average was 133.2%, which in turn was lower than the 138.8% average for the whole of the non-financial business economy.

The gross operating rate is the ratio of the gross operating surplus to turnover and is a measure of operating profitability; generally enterprises operating within distributive trades have low gross operating rates because their activity inherently leads to high turnover from purchasing and selling goods without transformation. For the EU-27's motor trades sector this rate was 4.2% in 2009, less than half the non-financial business economy average (9.7%) and lower than the distributive trades average (5.1%). In 2009, the EU-27's motor trades sector had the fifth lowest level of operating profitability (using this measure) among the NACE divisions within the EU-27's non-financial business economy.

Sectoral analysis

The sale of motor vehicles (Group45.1) was the largest subsector within the EU-27's motor trades sector, particularly in value added terms where it contributed more than half the sectoral total (50.9%). The second largest subsector was motor vehicle maintenance and repair (Group45.2) which employed close to two fifths of

the sectoral workforce and generated three tenths of value added. An analysis of the shares for the two largest subsectors – see Figure 1 – underlines the different characteristics of these activities: the sale of motor vehicles concerns the sale of expensive capital goods, while the maintenance and repair of motor vehicles provides labour-intensive services. The third largest subsector was the sale of motor vehicle parts and accessories (Group45.3) while by far the smallest subsector was the motorcycle distribution activity covering the sale, maintenance and repair of motorcycles as well as sales of related parts and accessories (Group45.4).

Apparent labour productivity was notably higher for the sale of motor vehicles subsector than for other subsectors in the EU-27 in 2009, at EUR39 thousand per person employed, close to the non-financial business economy average. Average personnel costs were also higher for this subsector, reaching EUR31.9 thousand per employee, nearly EUR2 thousand above the non-financial business economy average. In contrast, the motor vehicle maintenance and repair subsector recorded the lowest ratios among the four subsectors for both of these measures. When combining apparent labour productivity and average personnel costs to produce the wage-adjusted labour productivity ratio the four subsectors split into two pairs: ratios above the sectoral average were recorded for the two pure sales subsectors, namely the sale of motor vehicles and the sale of motor vehicle parts and accessories, while lower wage-adjusted labour productivity ratios were recorded for motor vehicle maintenance and repair and for motorcycle distribution. In all four subsectors the wage-adjusted labour productivity ratio was below the distributive trades and non-financial business economy averages.

There was far more diversity in the EU-27 gross operating rates of the four subsectors in 2009. The motor vehicle maintenance and repair subsector stood out from the others as its 11.9% gross operating rate was above the non-financial business economy average (9.7%), and was more than double the rate in the other subsectors. The lowest rate of 2.7% was recorded for the sale of motor vehicles; this was the lowest rate for all distributive trades NACE groups and the eighth lowest among the non-financial business economy NACE groups for which 2009 data are available.

Country analysis

Regardless of the motor trades subsector concerned Germany had the largest contribution to EU-27 value added in 2009, ranging from a 20.9% share for motorcycle distribution to a 32.7% share for the sale of motor vehicles. For the whole of the motor trades sector the German contribution to EU-27 sectoral value added averaged 29.2%, nearly double the next highest share of 15.2% in the United Kingdom. Among the Member States, Germany was also the most specialised country for motor trades in value added terms, as it generated 3.0% of its non-financial business economy value added in this sector in 2009. Also relatively highly specialised in motor trades were Belgium (where 2.8% of non-financial business economy value added came from this sector), Romania (2.7%) and Portugal (2.6%). The least specialised Member States were the Czech Republic, Slovakia, Ireland and Slovenia, where less than 1.5% of non-financial business economy value added stemmed from motor trades.

The relatively low wage-adjusted labour productivity ratio recorded for the EU-27's motor trades sector in 2009 was relatively widespread. Cyprus, the Czech Republic and Spain recorded ratios between 90% and 100% in 2009, indicating that apparent labour productivity was up to 10% lower than average personnel costs, while even lower wage-adjusted labour productivity ratios were recorded in Ireland (84.4%), Italy (80.4%) and Slovenia (49.6%). Only Romania and Germany recorded wage-adjusted labour productivity ratios for motor trades that were above their national non-financial business economy averages, with Romania recording the highest ratio among the Member States, at 234.6%.

Given the distributive nature of the motor trades sector, it is unsurprising that the gross operating rate was lower than the average for the whole of the non-financial business in all Member States in 2009. As was the case for the wage-adjusted labour productivity ratio, Romania recorded the highest gross operating rate (9.6%) for the motor trades sector in 2009, while Slovenia recorded a negative gross operating rate (-3.0%) and Ireland a rate of 0.0%.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of

non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the motor trades sector in the EU, as covered by NACE Rev.2 Division45. This division includes all activities related to motor vehicles (except their manufacture and renting) and also covers vans, caravans, motor homes, lorries, trailers, trucks. The activities concerned are the sale of new and second-hand vehicles, their repair and maintenance, and the sale of parts and accessories. Sales include both wholesale (own account and commission) and retail sales. Maintenance and repair also includes activities such as washing, polishing and the installation of parts and accessories. The same activities (sale, repair, maintenance, installation of parts and accessories) for motorcycles and mopeds are covered separately.

This NACE division is composed of four groups:

- the sale of motor vehicles (Group45.1);
- the maintenance and repair of motor vehicles (Group45.2);
- the sale of motor vehicle parts and accessories (Group45.3);
- the sale, maintenance and repair of motorcycles and related parts and accessories (Group45.4).

This division does not include the retail sale of automotive fuel and lubricating or cooling products (part of [retail trade](#) , Division47) or the renting of motor vehicles or motorcycles (included within [rental and leasing activities](#) , Division77).

Motorcycle and bicycle production statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers the manufacture of motorcycles and bicycles and other transport equipment, corresponding to NACE Groups 35.4 and 35.5, which are part of the [transport equipment](#) sector. The activities covered in this article are the manufacture of:

- motorcycles and bicycles (corresponding to NACE Group 35.4);
- miscellaneous transport equipment, such as wheelbarrows, hand-carts and luggage trucks (NACE Group 35.5).

	Enterprises (thousand)	Turnover (EUR million)	Value added (EUR million)	Persons employed (thousand)	Share in total (%)	
					Value added	Persons employed
Miscellaneous transport equipment (1)	3.0	11 519	2 727	64.5	100.0	100.0
Motorcycles and bicycles (2)	2.3	11 200	2 380	55.9	87.6	86.7
Other transport equipment n.e.c. (3)	0.7	1 041	337	8.6	12.4	13.3

Scooters with an engine capacity > 50 cm ³ but ≤ 250 cm ³	35.41.12.13	840	60	360	units	30
Motorcycles, and cycles fitted with an auxiliary motor, with an engine capacity ≤ 50 cm ³	35.41.11.00	706	-	530	units	-
Motorcycles with an engine capacity > 500 cm ³ but ≤ 800 cm ³	35.41.12.50	693	-	109	units	-

(1) Excluding products of a generic nature (other), sales of services such as repair, maintenance and installation; estimates; threshold of production value set at EUR 600 million; the rounding base indicates the magnitude of the rounding employed to protect confidential cells (in the case of PRODCOM code 35.41.12.70, the volume of production lies within the range +/- 90 000 units of the reported value).

Source: Eurostat (PRODCOM)

Table 3: Miscellaneous transport equipment (CPA Groups 35.4 and 35.5). Production of selected products, EU-27, 2007 (1)

Manufacture of motorcycles and bicycles

The EU-27's motorcycles and bicycles manufacturing subsector (NACE Group 35.4) consisted of 2.3 thousand enterprises which created EUR 2.4 billion of value added in 2006, equivalent to a 1.2% share of the transport equipment manufacturing (NACE Subsection DM) total. The sector employed 55.9 thousand persons, 1.8% of the transport equipment manufacturing total.

Italy was the largest producer of motorcycles and bicycles in the EU-27, with a 40.2% share of EU-27 value added and a 34.9% share of the workforce; Italy and Lithuania were the most specialised producers of motorcycles and bicycles within the EU-27 in terms of the sector's contribution to non-financial business economy (NACE Sections C to I and K) value added.

In 2007 motorcycles and bicycles manufacturing output in the EU-27 grew by 2.2%, following 1.8% growth in 2006: this was the first time since 1998 that output growth was recorded for two successive years.

In 2006 the EU-27's motorcycles and bicycles manufacturing subsector combined an apparent labour productivity of EUR 42.6 thousand per person employed with low average personnel costs (EUR 30.9 thousand per employee) to leave a wage-adjusted labour productivity ratio of 138.0%, the highest among the transport equipment manufacturing NACE groups. In most Member States⁸⁹ value added per person employed exceeded personnel costs per employee, the exceptions being Slovenia and France where the wage-adjusted labour productivity ratio was below 100%, and in Ireland where negative value added resulted in a large, negative wage-adjusted labour productivity ratio.

Manufacture of other transport equipment not elsewhere classified (n.e.c.)

The EU-27's other transport equipment manufacturing not elsewhere classified subsector (NACE Group 35.5) consisted of just under 0.7 thousand enterprises in 2006, which employed 8.6 thousand persons. In 2005 the value added of this subsector in the EU-27 was EUR 0.3 billion. This subsector represented just 0.2% and 0.3% respectively of transport equipment manufacturing value added and employment.

Germany generated EUR 186.7 million of value added in this subsector, far ahead of the next largest Member State which was the United Kingdom with EUR 59.1 million of value added.

The EU-27's other transport equipment n.e.c. subsector recorded apparent labour productivity of EUR 38.8 thousand per person employed in 2005, and average personnel costs of EUR 34.9 thousand per employee in 2006.

⁸⁹Poland, 2005; Estonia, Cyprus, Latvia, Luxembourg, Malta, the Netherlands and Romania, not available.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include the [PRODCOM](#) statistics on the production of manufactured goods.

Context

The transport equipment manufacturing sector is central to economic development, as it provides the means for transporting both individuals and goods. Demand for transport equipment has risen as the volume of goods transported and the distance travelled by passengers have expanded greatly – see the article on [Transport and storage statistics] for information on transport flows.

The issue of sustainable development is likely to play an important role in future product developments, as transport equipment manufacturers try to meet demands for more environmentally friendly transport solutions, for example, engines with lower fuel consumption or emissions.

Most transport equipment manufacturing activities are structured on the basis of complex pyramidal relationships between major manufacturers and several tiers of component suppliers, ranging from systems suppliers down to very small, specialised manufacturers that may provide a single component for a vehicle. It is common to find clusters of enterprises concentrated in regions around the leading producers.

Notes

Non-energy mining and quarrying statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) analysing the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). The present article covers the non-energy mining and quarrying sector, which consists of:

- underground and open-cast mining of ferrous and non-ferrous metal ores, corresponding to [NACE Division 13](#);
- mining and quarrying of other non-energy producing materials, corresponding to [NACE Division 14](#).

It also treats the extraction of a variety of materials traditionally used for construction purposes (such as sand, clay or stone), and of salt and a range of other chemical and fertiliser minerals. Together these NACE divisions make up the non-energy mining and quarrying sector.

Note that this article covers only extractive activities, and not the [processing of fuel](#), the [manufacture of non-metallic mineral products](#), nor the [network supply and distribution of electricity, gas and steam](#).

	Enterprises (thousand)	Turnover (EUR million)	Value added (EUR million)	Persons employed (thousand)	Share in total (%)	
					Value added	Persons employed

Table 2: Mining and quarrying, except of energy producing materials (NACE Subsection CB). Structural profile: ranking of top five Member States in terms of value added and persons employed, 2006

Source: Eurostat (SBS)

Map 1: Mining and quarrying, except of energy producing materials (NACE Subsection CB). Persons employed in mining and quarrying, except of energy producing materials (NACE CB) as a proportion of those employed in the non-financial business economy (NACE Sections C to I and K) (%)

There were about 18300 enterprises with non-energy mining and quarrying (NACE Subsection CB) as their main activity in the EU-27 in 2006, and they generated EUR 19.5 billion of value added and employed 288.5 thousand persons. Non-energy mining and quarrying is a relatively small industrial activity, accounting for just 0.3% of the value added generated within the EU-27's non-financial business economy (NACE Sections C to I and K) or 0.2% of its workforce. Relative to mining and quarrying (NACE Section C) as a whole, non-energy mining and quarrying accounted for 22.0% of value added and 39.3% of the workforce.

The enterprise size structure of the non-energy mining and quarrying sector is the average of two extremes. Overall, it is dominated by locally-based small and medium-sized enterprises that operate principally within the other mining and quarrying subsector (NACE Division 14), while there were just 300 enterprises active within the mining of metal ores (NACE Division 13) in the EU-27 in 2006. The difference in the number of enterprises was a factor of 55 in favour of other mining and quarrying subsector, while the corresponding ratio for value added suggested that other mining and quarrying activities were 2.9 times as large. At the more detailed level of NACE groups, the quarrying of sand and clay (NACE Group 14.2) was clearly the largest activity covered by this article, accounting for close to half of all enterprises (52.5%), value added (48.8%), investment in tangible goods (51.4%) and employment (48.5%).

There were seven principal producers of non-energy mining and quarrying products within the EU-27; the six largest Member States (in terms of population) and Sweden. Each of these generated between 9.5% and 12.9% of the EU-27's value added in this sector (Polish data are for 2005), with the highest level recorded in the United Kingdom (EUR 2.5 billion). Bulgaria, Poland (both 2005), Sweden, Ireland, Portugal and Romania were clearly the most specialised Member States in value-added terms – each of these countries reported that their non-energy mining and quarrying sector contributed at least twice the EU-27 average share to value added within their respective non-financial business economies.

In employment terms, the Polish workforce of 36400 (again for 2005) was equivalent to 12.3% of the EU-27 total and was followed by Germany (12.0%), whilst Romania (also 2005) as well as the United Kingdom, Italy, Spain and France each had between 28000 and 30000 persons employed in the sector. Employment in the non-energy mining and quarrying sector was also relatively high in Sweden, where it stood at 8100 persons in 2006. The regional specialisation of non-energy mining and quarrying activities, based on the non-financial business economy employment share of this sector, is shown in Map 1. Relatively high shares were recorded for several regions on the periphery of the EU, notably Övre Norrland in northern Sweden (where 4.0% of the non-financial business economy workforce was employed in non-energy mining and quarrying activities), northern regions of Finland, several regions in Bulgaria, Greece and Romania, central and southern Portugal, as well as Cornwall and Devon in the United Kingdom.

The last decade has seen almost continual growth for the EU-27 index of production for non-energy mining and quarrying, averaging 2.1% peryear during the ten years to 2007, and only interrupted by a 2.3% reduction in 2001. The performance of the overall index is closely tied to the evolution of output from the mining of stone and the mining of sand and clay. In contrast, the index of production for the mining of metal ores resembles more closely that for [energy-producing materials](#) , with output falling.

The EU-27 employment index for non-energy mining and quarrying fell in each of the last nine years, with reductions averaging 2.7% per year. More detailed information (available since 2000) shows that the largest reductions in employment were recorded for the mining of metal ores (averaging -14.6% per year between 2000 and 2007 – equivalent to an overall fall of more than 60%). During the same period, the employment index for other mining and quarrying fell to a low in 2004, since when three consecutive increases were registered.

Other mining and quarrying experienced uninterrupted domestic output price growth in the EU-27, averaging 2.7% per year in the ten years to 2007. Prices generally rose at a fairly uniform pace, although there was a high increase of 6.5% in 2002 and some evidence of accelerating price growth in 2006 and 2007 (as year-on-year increases of 3.0% and 3.8% were registered). A shorter time series is available for the mining of metal ores, with price fluctuations considerably greater. This reflected contract negotiations between iron ore mining and steel making enterprises, as well as rising global demand for metals in general, driven by unprecedented demand from rapidly emerging economies, such as China, Brazil and India. EU-27 output prices for metal ores stood almost 160% higher in 2007 than they were in 2000 – by far the biggest increase across any of the NACE divisions within the industrial economy.

Expenditure and productivity

	(EUR million)			(EUR thousand per person)	
	Personnel costs	Purchases of goods & services	Investment in tangible goods	Apparent labour productivity	Average personnel costs
Mining and quarrying, except of energy producing materials	8 304	30 369	4 433	67.5	30.2
Mining of metal ores	1 186	3 143	1 043	109.7	26.6
Other mining and quarrying	7 117	27 226	3 390	59.5	30.9

Source: Eurostat (SBS)

Table 3: Mining and quarrying, except of energy producing materials (NACE Subsection CB). Expenditure, productivity and profitability, EU-27, 2006

The EU-27's non-energy mining and quarrying sector recorded an [investment rate](#) (the ratio of investment to value added) of 22.8% in 2006, somewhat higher than the average for the whole of the non-financial business economy (18.4%). The capital-intensive nature of this activity is evident when looking at its share of total investment within the non-financial business economy (0.4%), which was almost twice as high as its share of the non-financial business economy workforce (0.2%).

Nevertheless, personnel costs accounted for a relatively high proportion (21.5%) of total operating expenditure in the EU-27's non-energy mining and quarrying sector in 2006, compared with an average of 16.1% for the whole of the non-financial business economy. This relatively high share was based on average personnel costs of EUR 30200 per [employee](#) , slightly above the non-financial business economy average of EUR 28800 per employee.

In contrast, the EU-27's non-energy mining and quarrying sector recorded an apparent [labour productivity](#) of EUR 67500 per person employed in 2006, which was 55% higher than the non-financial business economy average (EUR 43500 per person employed). Combining these two ratios into the wage-adjusted labour productivity ratio shows the relationship between value added and personnel costs per head, and indicates that value added per person employed in the EU-27's non-energy mining and quarrying sector was equivalent to 223.5% of the average personnel costs in 2006, significantly higher than the non-financial business economy average (151.1%).

Among the NACE groups that make-up the non-energy mining and quarrying sector, the most capital-intensive and productive activity was the mining of iron ores subsector. The quarrying of sand and clay was the only other activity to record labour productivity above the sectoral average, while the mining of non-ferrous metals was the only other activity to report a wage adjusted labour productivity ratio above the sectoral average (resulting from average personnel costs that were less than two thirds the non-financial business economy average).

The highest level of [wage-adjusted labour productivity](#) within the non-energy mining and quarrying sector was recorded in Sweden (384.5%) – a country specialised in the mining of iron ores – where apparent labour productivity was close to four times the average personnel costs. Only Slovakia and Romania (2005) recorded wage-adjusted labour productivity ratios in the non-energy mining and quarrying sector that were below the average ratio for the non-financial business economy.⁹⁰

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Context

The global mining and quarrying sector is characterised by a relatively small number of international enterprise groups, that operate across the continents – sometimes with only their head office in the EU or another developed economy. These large-scale producers are complemented by a large number of smaller enterprises, typically serving a local market in low value, widely available products, often for use in construction. The location of mining and quarrying activity generally reflects the spatial distribution of mineral deposits. However, there can be considerable cost differences between mines, for example, in relation to the depth at which deposits are found, or whether they are on land or at sea. Aside from geographical and geological cost differences, the decision of whether or not to (re-)open a mine may also depend, among others, on global, commodity prices, as well as regulations concerning the environmental impact of mining or the disposal of its waste.

The EU aims to become a low-carbon, energy-efficient economy in the coming years. The integrated energy and climate change policy laid out in December 2008 aims to cut [greenhouse gases](#) by 20%, reduce energy consumption by 20% through increased energy efficiency and to meet 20% of the EU's energy needs from [renewable sources](#) by 2020 – these goals will have implications on the way extractive activities operate.

Another important aspect in relation to this sector concerns the security of supply for downstream activities. Aside from well-publicised geopolitical disputes which have threatened the supply of crude petroleum or natural gas to European markets, there are also a large number of non-energy related minerals, which are often essential for downstream manufacturing activities. There is no indigenous supply for many of these, with the extraction of construction materials being one of the few areas where the EU is largely self-sufficient.

In November 2008 the European Commission ([COM\(2008\) 699](#)) published a raw materials initiative, stating that access to and the affordability of many raw materials is likely to play an important role in determining the competitiveness and future growth prospects of the EU economy. As with many energy producing materials, the EU is also highly dependent on a range of strategically important non-energy minerals and ores that are imported from a range of countries, in particular: China, the Russian Federation, Australia and a range of countries in Africa and South America.

⁹⁰Belgium, Bulgaria, Greece, Cyprus, Poland and Romania: data from 2005; Ireland, Malta, the Netherlands and Slovenia: data not available.

The EU is particularly dependent on imports of metallic minerals. While some of these metals are needed only in tiny quantities, they can be essential for the production of technologically sophisticated products, in particular, new areas of development related to environmental technologies (for example, hydrogen-fuel based cars require platinum-based catalysts and electric-hybrid cars need lithium batteries). A range of European [manufacturing](#) activities, most notably the chemicals, motor vehicles, aerospace, machinery and equipment sectors all depend on supplies of raw materials such as these. Aside from these technologically-driven uses, industrial and construction minerals are often further processed in downstream sectors, for example, the manufacture of glass, concrete, or agricultural chemicals, as well as being used directly within the construction sector. The EU is self-sufficient in most construction minerals, in particular aggregates, and is also a leading producer of feldspar, gypsum, potash and natural stone.

Notes

Non-specialised in-store retail trade statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers non-specialised in-store retail trade, corresponding to NACE Groups 52.11 and 52.12, which are part of the [retail trade and repair](#) sector. Non-specialised retailers offer consumers the opportunity to buy a broader range of products at a sole point of purchase (for example, supermarkets, hypermarkets or convenience stores). The activities covered in this article are retail sales in non-specialised stores of:

- food, beverages and tobacco (NACE Class 52.11);
- non-food products (NACE Class 52.12), principally department stores that stock a general line of merchandise.

	Enterprises (thousand)	Turnover (EUR million)	Value added (EUR million)	Persons employed (thousand)	Share in total (%)	
					Value added	Persons employed
Non-specialised in-store retailing (1)	588.8	900 000	140 000	6 176.1	100.0	100.0
Non-specialised in-store retailing, with food beverages or tobacco predominating (2)	479.1	800 000	110 000	5 200.0	84.6	84.2
Other non-specialised in-store retailing	109.8	109 891	24 941	1 976.1	17.8	15.8

Source: Eurostat (585)

Table 2: Retail sale in non-specialized stores (NACE Group 52.1). Structural profile: ranking of top five Member States in terms of value added and persons employed, 2006

The [EU-27](#)'s non-specialised in-store retailing sector (NACE Group 52.1) generated EUR 900 billion of [turnover](#) in 2006 and EUR 140 billion of [value added](#) while [employing](#) 6.2 million persons. As such, it accounted for 42.3% of the turnover and 33.5% of the value added created by retail trade and repair (NACE Division 52) in 2006, while some 35.3% of the retail trade and repair workforce was concentrated in this sector. The non-specialised in-store retailing sector's workforce had a relatively high proportion of paid employees, 90.9% in the EU-27, 11.2% higher than the retail trade and repair average.

In total, almost 0.6 million [enterprises](#) were active in this sector, just 15.5% of the retail trade and repair total, indicating a relatively large average size, particularly in turnover terms: in 2006, average turnover per enterprise in the EU-27's non-specialised in-store retailing sector was just over EUR 1.5 million, approximately two and a half times the average for retail trade and repair. With the exceptions of Bulgaria and Romania, in all Member States⁹¹ the average turnover per enterprise was higher in the non-specialised in-store retailing

⁹¹Bulgaria and Poland, 2005; Malta and the Netherlands, not available.

sector than in the retail trade and repair sector as a whole. Luxembourg recorded the highest average turnover per enterprise (EUR 10.8 million). However, a comparison in relative terms showed French and Spanish non-specialised in-store retailers to be more than six times as large as the retail trade and repair average, while in Lithuania, Belgium and Luxembourg they were more than four times as large.

Turning to the two NACE classes that make up the sector, the wealth generated within non-specialised in-store retailing mainly came from retailers with food, beverages or tobacco predominating (NACE Class 52.11), with EUR 800 billion of turnover and EUR 110 billion of value added recorded in 2005, more than four fifths of the sectoral total in both cases. This subsector was dominant in all Member States⁹² except for Slovakia, frequently generating more than four fifths of sectoral turnover.

The United Kingdom was by far the largest contributor to EU-27 value added and employment in the non-specialised in-store retailing sector, contributing more than one fifth of the EU-27 total for both of these measures; Germany and France were the only other Member States with 10% or more of the EU-27 total. The dominance by the United Kingdom resulted in it being the third most specialised Member State⁹³ in this sector, in value added terms, as 3.2% of its non-financial business economy value added was generated in the non-specialised in-store retailing sector, a share only surpassed in Slovenia and Lithuania. According to the same measure, the non-specialised in-store retailing sector was least developed in Bulgaria, where it contributed just 1.4% (2005) of non-financial business economy value added.

[Short-term statistics](#) show that over the period 1998 to 2006 there was consecutive year on year growth in the volume of sales index for EU-27 non-specialised in-store retailing. This growth averaged 3.8% per year, marginally above the retail trade and repair average of 3.6% per year. Growth was faster in the subsector concerning non-specialised in-store retailing with food, beverages or tobacco predominating, where it averaged 4.4% per year, more than double the rate (2.1% per year) recorded for non-specialised in-store retailing with non-food products predominating.

Expenditure and productivity

The EU-27 retail sales in non-specialised stores sector was responsible for a large part of retail trade and repair gross [tangible investment](#) : the level of investment reached EUR 28.6 billion in 2006, close to half (46.7%) of the retail trade and repair total. The resulting [investment rate](#) (investment as a percentage of value added) was 20.4%, the highest rate among the retail trade and repair NACE groups, and the only one of these to register an investment rate above the non-financial business economy average (18.4%).

An analysis of expenditure in the EU-27 shows that [personnel costs](#) accounted for around 11.1% of [operating expenditure](#) in this sector, slightly below the retail trade and repair average (12.3%). The share of personnel costs was notably higher for non-specialised in-store retailing with non-food products predominating (15.9%).

The apparent labour productivity ratio of the EU-27's non-specialised in-store retailing sector in 2006 was EUR 22.7 thousand per person employed, while average personnel costs were EUR 17.8 thousand per employee, resulting in a [wage-adjusted labour productivity ratio](#) of 127.3%. These figures were all similar to, but slightly lower than, those recorded for retail trade and repair as a whole. The subsector concerning non-specialised in-store retailing with non-food products predominating recorded a higher wage-adjusted labour productivity ratio, 140.0% in 2005, whereas in the larger subsector with food, beverage and tobacco products predominating the ratio was 126.0%. The wage-adjusted labour productivity ratio for non-specialised in-store retailing in 2006 ranged among the Member States⁹⁴ from below 100% in Italy (97.5%) to 177.4% in Slovakia.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

⁹²Bulgaria and Poland, 2005; Denmark, Malta and the Netherlands, not available.

⁹³Bulgaria, Cyprus, Poland and Romania, 2005; Malta and the Netherlands, not available.

⁹⁴Bulgaria and Poland, 2005; Malta and the Netherlands, not available.

Context

Retailing is typically the final stage of distribution between producers and consumers. Since the development of the Internet, there has been an increasing use of commerce via the web. As such, there has been a gradual shift from traditional methods of purchasing from stores or markets to purchasing remotely. According to Eurostat's information society statistics, some 12% of the turnover of distributive trades (including motor trades (NACE Division 50) and wholesale trades (NACE Division 51), as well as retail trade and repair) enterprises with ten or more persons employed was derived from [e-commerce](#) in 2008. According to the same source, one quarter of the EU-27's population ordered or bought goods or services for private use through the Internet in 2008 (during the three months preceding the survey). Note that these figures refer to goods and services supplied to individuals by all sectors of the economy, not just enterprises that are specialised in retail sales.

In October 2008, the [European Commission](#) put forward a [proposal COM\(2008\) 614](#) for a Directive on consumer rights, to try to make purchases easier and safer, whether in-store or not. The proposal covers the provision of price information, protection against late delivery and non delivery, as well as setting out rights on issues such as cooling-off periods, returns, refunds, repairs and guarantees and unfair contract term.

Non-specialised retailers offer consumers the opportunity to buy a broader range of products at a sole point of purchase (for example, supermarkets, hypermarkets or convenience stores). Large, non-specialised food retailers, in particular, may have greater price flexibility, as they are able to accept lower [profit](#) margins on certain products, as well as exerting greater purchasing power on their suppliers; furthermore, they may have their own integrated wholesale activities.

Non-specialised wholesale trade statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers non-specialized wholesale trade, corresponding to NACE Group 51.9, which is part of the [wholesale trade](#) sector. The activities covered in this article are:

- the specialised own-account wholesaling of products not covered in the other sub-sectors of the wholesale trade sector;
- non-specialised wholesaling, where enterprises resell a variety of products.

	Highest value added (1)		Largest number of persons employed (1)		Most specialised: share in non-financial business economy (%) (2)			
	Country	(EUR million)	(% of EU-27)	Country	(thousand)	(% of EU-27)	Country	Value added

Table 1: Other wholesale (NACE Group 51.9). Structural profile: ranking of top five Member States in terms of value added and persons employed, 2006

Main statistical findings

Structural profile

Turnover in the EU-27's other wholesale trade (NACE Group 51.9) sector in 2006 was EUR 209.7 billion, therefore contributing 4.6% of wholesale trade (NACE Division 51) turnover. The other wholesale trade sector generated EUR 26.6 billion of **value added**, which was equivalent to 5.1% of the wholesale trade total. According to both of these **output** measures, this was the second smallest wholesale trade NACE group. Its biggest contribution to the wholesale trade total was in terms of **employment**, where the 664.7 thousand persons employed in the other wholesale trade sector accounted for 6.7% of the wholesale trade workforce.

The EU-27's other wholesale trade sector was dominated by three Member States, with the United Kingdom, Germany and Poland (2005) collectively contributing around three fifths of total value added and employment. Poland's share of the EU-27's workforce in this sector was particularly significant, more than one third (34.2%) in 2005. Unsurprisingly, in value added terms Poland was the most specialised Member State⁹⁵; Slovakia and Hungary were also relatively specialised, with this sector contributing 2.3% of national **non-financial business economy** (NACE Sections C to I and K) value added.

Expenditure and productivity

The level of investment recorded in the other wholesale trade sector was valued at EUR 3.4 billion in 2006, 6.4% of the wholesale trade total. Although this was relatively small in value terms, the **investment rate** (gross **tangible investment** relative to value added) was 12.8%, the second highest among wholesale trade activities.

An analysis of operating expenditure in the other wholesale trade sector showed that 6.3% of expenditure was used for **personnel costs** in the EU-27, in line with the 6.5% average for wholesale trade. Average personnel costs were particularly low in this sector, just EUR 21.7 thousand per employee, equivalent to two thirds of the

⁹⁵Bulgaria, Cyprus, Poland and Romania, 2005; Malta and the Netherlands, not available.

wholesale trade average. While the apparent [labour productivity](#) (EUR 40.0 thousand per person employed) was also the lowest among the wholesale trade activities presented in sub-sectors of the wholesale trade sector, it was equivalent to three quarters of the wholesale trade average. As a consequence of the particularly low average personnel costs, the EU-27's other wholesale trade sector had a [wage-adjusted labour productivity ratio](#) of 184.9%, 25.1 percentage points above the wholesale trade average, the highest of the wholesale trade NACE groups, and the fourth highest among the non-financial services (NACE Sections G to I and K) NACE groups.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Context

The activities in NACE Division 51 cover all wholesale trade except that [concerning motor vehicles and motorcycles](#): the wholesaling of automotive fuel is considered as a wholesale trade rather than a motor trade. This article covers resale (sale without transformation) of new and used products, as well as wholesale activities carried out on a fee or contract basis.

The wholesaling activity consists of selling to retailers or to industrial, commercial, institutional and professional users. Wholesalers can act on a [fee or contract basis as agents](#) or for their own account, buying and selling goods. The own-account wholesale sub-sectors distinguish the types of product in which the wholesaler is specialised ([agricultural products](#), [consumer goods](#), [intermediate goods](#), [machinery and equipment](#)), while specialised wholesalers of other products are included in non-specialised wholesalers (this article).

In the supply chain, wholesalers are located between producers and users, providing know-how and knowledge in markets for which they have expertise. Competition within the wholesale trade activity is often centred on providing more efficient services or more sophisticated value added services. Wholesalers can provide a range of services from basic storage and break of bulk, sorting, grading and logistics to pre- and post-production operations (for instance, labelling, packaging, bottling and installation).

Notes

Non-store retail trade statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers non-store retail trade, corresponding to NACE Group 52.6, which is part of the [retail trade and repair](#) sector. The activities covered in this article are retail sales made via:

- stalls;
- markets;
- door-to-door sales;
- remote sales made via:
 - mail order;
 - mobile sales;
 - vending machines;
 - the Internet;
 - home shopping channels.

This article does not include retail enterprises that also use remote-selling, but not as their principal activity.

	Enterprises (thousand)	Turnover (EUR million)	Value added (EUR million)	Persons employed (thousand)	Share in total (%)	
					Value added	Persons employed
Retail sale not in stores	540.0	100 000	19 000	920.0	100.0	100.0
Retail sale via mail order houses	31.0	50 000	8 794	194.4	46.3	21.1
Retail sale via stalls and markets	366.0	19 041	3 999	441.6	21.0	48.0
Other non-store retail sale	143.0	31 000	6 500	280.0	34.2	30.4

Table 2: Retail sale not in stores (NACE Group 52.6). Structural profile: ranking of top five Member States in terms of value added and persons employed, 2006

Retail sales not in-stores (NACE Group 52.6) was the main activity of an estimated 540.0 thousand enterprises, which generated EUR 100 billion of turnover in the EU-27 in 2006, representing 4.4% of the turnover within the retail trade and repair sector (NACE Division 52). EU-27 value added was EUR 19 billion, or 4.5% of the retail trade and repair total and there were an estimated 920.0 thousand persons employed, equivalent to 5.3% of the retail trade and repair workforce. Of this workforce, just 49.5% were paid employees: this was the lowest share of paid employees of all of the NACE groups within the non-financial business economy (with 2005 or 2006 data available).

Across the three NACE classes that make up retail sales not in stores, retail sales via mail order houses (NACE Class 52.61) was the largest activity in terms of turnover in 2005 with just over half the sectoral total. In contrast, retail sales via stalls and markets (NACE Class 52.62) had the smallest share of sectoral turnover. The activity of retail sales via mail order houses was relatively important in turnover terms in several of the larger Member States (France, Germany and the United Kingdom), as well as the Nordic Member States, and most of all Austria.

Among the Member States⁹⁶, Germany contributed more than one quarter of the EU-27's turnover and value added, and the United Kingdom also had a relatively high share for these two indicators, more than one fifth. Both of these larger Member States figured among the most specialised in value added terms, behind Greece and Lithuania.

Expenditure and productivity

Gross tangible investment in the EU-27's retail trade not in stores sector was EUR 2 billion in 2006, 3.3% of the retail trade and repair total. The investment rate was 10.5% and therefore 4.1 percentage points lower than the retail trade and repair average.

An analysis of expenditure shows that this sector had the highest share (90.3%) of purchases of goods and services in operating expenditure among the retail trade and repair activities presented in articles on the sub-sectors of the retail trade and repair sector. The correspondingly low share dedicated to personnel costs can to a large extent be explained by the very low share of paid employees within the workforce. This characteristic of the sector may also account to some extent for the low wage-adjusted labour productivity ratio: for retail sales not in stores this was 96.9% in the EU-27 in 2006, reflecting a level of apparent labour productivity (EUR 20.7 thousand per person employed) that was insufficient to cover the average personnel costs (EUR 21.3 thousand). The activity of retail sales not in stores was the only NACE group within the whole of the non-financial business economy where this ratio was below parity (100%) for the EU-27 in 2006.

Data sources and availability

The main part of the analysis in this article is derived from structural business statistics (SBS), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

⁹⁶Bulgaria, Luxembourg and Poland, 2005; Malta, not available.

Context

Retailing is typically the final stage of distribution between producers and consumers. Since the development of the Internet, there has been an increasing use of commerce via the web. As such, there has been a gradual shift from traditional methods of purchasing from stores or markets to purchasing remotely. According to Eurostat's information society statistics, some 12% of the turnover of distributive trades (including motor trades (NACE Division 50) and wholesale trades (NACE Division 51), as well as retail trade and repair) enterprises with ten or more persons employed was derived from [e-commerce](#) in 2008. According to the same source, one quarter of the EU-27's population ordered or bought goods or services for private use through the Internet in 2008 (during the three months preceding the survey). Note that these figures refer to goods and services supplied to individuals by all sectors of the economy, not just enterprises that are specialised in retail sales.

In October 2008, the [European Commission](#) put forward a [proposal COM\(2008\) 614](#) for a Directive on consumer rights, to try to make purchases easier and safer, whether in-store or not. The proposal covers the provision of price information, protection against late delivery and non delivery, as well as setting out rights on issues such as cooling-off periods, returns, refunds, repairs and guarantees and unfair contract term.

Main statistical findings

Structural profile

There were 362 thousand enterprises operating in the office and business support activities (Division82) sector in the EU-27 in 2009. Together they employed 1.86 million persons, equivalent to 1.4% of the non-financial business economy (Sections B to J and L to N and Division95) workforce or 15.4% of those employed in administrative and support services (Section N). The office and business support activities sector generated EUR67000 million of value added which was 1.2% of the non-financial business economy total or nearly one fifth (19.1%) of the administrative and support services total.

The apparent labour productivity of the EU-27's office and business support activities sector in 2009 was EUR36 thousand of value added per person employed, which although below the non-financial business economy average of EUR41.6 thousand was higher than the administrative and support services average of EUR29 thousand. Average personnel costs within the EU-27's office and business support activities sector were, at EUR28.9 thousand per employee, also slightly lower than the average for the whole of the non-financial business economy (EUR30.0 thousand per employee), but some EUR8 thousand higher than the administrative and support services average. The wage-adjusted labour productivity ratio which combines these two previous indicators and shows the extent to which value added per person employed covers average personnel costs per employee stood at 126.1% for the EU-27's office and business support activities sector in 2009, which was below the averages registered for the non-financial business economy (138.8%) and administrative and support services (139.1%).

The gross operating rate which shows the relationship between the gross operating surplus and turnover is one measure of profitability; it stood at 12.0% for the EU-27's office and business support activities sector in 2009, which was 2.3 percentage points above the non-financial business economy average, but 3.2 percentage points lower than the average rate for administrative and support services.

Sectoral analysis

Almost three out of every four (72.4%) of the enterprises within the EU-27's office and business support activities sector in 2009 were classified within business support service activities (Group82.9). The second largest subsector in terms of enterprises was office administrative and support activities (Group82.1), with a 16.9% share. This was slightly more than double the enterprise share recorded for the organisation of conventions and

trade shows (Group82.3), while the smallest number of enterprises (2.1% of the sectoral total) was registered for the activities of call centres (Group82.2).

The analysis of value added for the EU-27's office and business support activities sector in 2009 confirmed the position of business support service activities as the largest subsector, as it accounted for 69.7% of sectoral value added. The share of value added for the activities of call centres was 14.8%, clearly above those of the two other subsectors – which were quite similar – 8.2% for the organisation of conventions and trade shows and 6.9% for office administrative and support activities.

The pattern observed for value added was reinforced when analysing the breakdown of the EU-27's office and business support activities workforce. The relative weight of business support service activities was lower still (61.8%) and the difference was taken up by the activities of call centres, whose share in sectoral employment reached 22.5%.

These differences in the relative weights of each subsector according to whichever measure of size was being analysed were, as a consequence, also apparent when analysing the average employment size of enterprises within the EU-27's office and business support activities sector. Enterprises whose principal activity was that of call centres averaged employment of 54.8 persons in 2009. The average size of enterprises was much lower for the three remaining subsectors: for the business support service activities subsector and the organisation of conventions and trade shows subsector the average was 4.4 persons employed per enterprise; for the office administrative and support activities subsector this ratio was 2.6 persons per enterprise.

There were also relatively large differences in relation to apparent labour productivity – which is based upon the average value added generated by members of the workforce. EU-27 apparent labour productivity across the four subsectors that compose the office and business support activities sector peaked in 2009 at EUR41 thousand per person employed for business support service activities, just EUR0.6 thousand lower than the non-financial business economy average. Apparent labour productivity for the organisation of conventions and trade shows was also relatively close to the non-financial business economy average, at EUR39 thousand of value added per person employed. This contrasted with the apparent labour productivity of the office administrative and support activities subsector (EUR29 thousand) and the activities of call centres subsector (EUR24 thousand).

EU-27 average personnel costs per employee peaked in 2009 at EUR32.1 thousand per employee for the organisation of conventions and trade shows, which was just ahead of business support service activities (EUR31.2 thousand) and office administrative and support activities (EUR29.4 thousand); all three of these values were closely situated around the non-financial business economy average of EUR30.0 per employee. The call centres subsector was therefore something of an exception, as its average personnel costs were much lower, at EUR22.2 thousand per employee.

The combination of the previous two indicators results in the wage-adjusted labour productivity ratio. This was relatively low for all four subsectors within the EU-27's office and business support activities sector in 2009 and consistently below the non-financial business economy average (138.8%). Wage-adjusted labour productivity ratios varied from a high of 130.0% for the business support service activities subsector down to 97.6% for office administrative and support activities – where the value added generated per person employed did not cover average personnel costs per employee.

For the gross operating rate, the EU-27's office administrative and support activities subsector (12.9%) and the business support service activities subsector (14.3%) both posted gross profitability rates that were above the non-financial business economy average (9.7%) in 2009. The profitability (based on this measure) of the organisation of conventions and trade shows subsector (9.3%) was close to the non-financial business economy average, while call centres posted a relatively low gross operating rate (5.0%).

Country analysis

Just over one quarter (25.3%) of the EU-27's value added within the office and business support activities sector in 2009 was generated in the United Kingdom. Value added in the United Kingdom was EUR16926 million, while Germany and France were the only other Member States to record figures above EUR10000. The United Kingdom was also the Member State with the highest degree of specialisation in this sector, in value added terms, as its office and business support activities sector contributed 2.0% of non-financial business economy value added (compared with an EU-27 average of 1.2%). France and Portugal were also relatively specialised

in office and business support activities, as this sector provided 1.5% of their non-financial business economy added value.

An analysis of the number of persons employed shows that Germany had by far the largest workforce among the Member States, as the 420.7 thousand persons engaged within the office and business support activities sector represented 22.6% of the EU-27 total. This was considerably higher than for the remaining Member States, as the United Kingdom (15.6%), Italy (13.9%), Spain (12.7%) and France (12.0%) were the only other countries to record double-digit shares of the EU-27 total; these five Member States jointly accounted for in excess of three quarters of the office and business support activities workforce.

Most Member States reported relatively low apparent labour productivity for the office and business support activities sector in 2009, with productivity levels below their non-financial business economy averages. The only countries to break this pattern were Cyprus, Latvia, Slovakia and the United Kingdom; for the latter, apparent labour productivity was almost one quarter higher than the non-financial business economy average. The United Kingdom also recorded the highest level of apparent labour productivity within the office and business support activities sector, at EUR58.5 thousand of added value per person employed in 2009.

Slovakia and the Netherlands were the only Member States to report a wage-adjusted labour productivity ratio for the office and business support activities sector that was higher than their national average for the non-financial business economy in 2009 (and this by no more than 5%). Slovakia also recorded the highest level of wage-adjusted labour productivity at 172.3%. In contrast, there were three Member States where wage-adjusted labour productivity ratios for the office and business support activities sector were below 100%, indicating that the value added generated per person employed did not cover average personnel costs per employee. The difference in Italy was minimal, as the ratio stood at 99.5%, however, the wage-adjusted labour productivity ratio was considerably lower in Slovenia (88.9%) and even more so in Sweden (74.1%).

There was a wide range in gross operating rates between the Member States for the office and business support activities sector in 2009, ranging from a high of 19.8% for the United Kingdom to a low of -10.2% for Sweden; the negative rate that was recorded in Sweden resulted from total personnel costs exceeding the added value that was generated in the office and business support activities sector. In the majority of the Member States, the gross operating rate for the office and business support activities sector was higher than for the non-financial business economy as a whole; this pattern held true for 16 of the Member States for which data are available. Among the seven exceptions, Spain, Ireland and Sweden were the only countries where the profitability of the office and business support activities sector was considerably lower than for the non-financial business economy as a whole.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the office and business support activities sector in the EU, as covered by NACE Rev.2 Division82. This division includes the provision of a range of day-to-day office administrative services, as well as ongoing routine business support functions for others, on a contract or fee basis. This division also includes all support service activities typically provided to businesses not elsewhere classified.

Combined office administrative service activities include the provision of a combination of day-to-day office administrative services, such as reception, financial planning, billing and record keeping, personnel and mail services for others on a contract or fee basis. Photocopying, document preparation and other specialised office support activities concerns a variety of specialised office support activities, such as typing and word processing, secretarial support services, letter or resumé writing, or the provision of mailbox rental.

Activities of call centres include both inbound call centres (answering calls) and outbound call centres (to sell or market goods or services to potential customers), regardless of whether these use human operators, automatic call distribution, computer telephone integration, interactive voice response systems or similar methods.

The organisation of conventions and trade shows also includes the organisation, promotion and/or management of events, such as business and trade shows, conventions, conferences and meetings, whether or not including the management and provision of the staff to operate the facilities in which these events take place.

Activities of collection agencies and credit bureaus include the collection of payments for claims and their remittance to clients, such as bill or debt collection services. Also included are the activities of compiling information, such as credit and employment histories of individuals and credit histories of businesses, and providing this information to financial institutions, retailers, or others who have a need to evaluate the creditworthiness of people and businesses. Packaging activities may be performed on a fee or contract basis and include the bottling of liquids (for example, beverages and food), the packaging of solids (blister packaging, foil-covered and so on), security packaging of pharmaceutical preparations, labelling, stamping and imprinting, parcel-packing and gift-wrapping. Other business support service activities not elsewhere classified include a wide range of support activities, including: verbatim reporting and stenotype recording of live legal proceedings and transcribing subsequent recorded materials; real-time (simultaneous) closed captioning of live television performances of meetings or conferences; address bar coding services; bar code imprinting services; fundraising organisation services on a contract or fee basis; repossession services; parking meter coin collection services; activities of independent auctioneers; the administration of loyalty programmes; other support activities typically provided to businesses not elsewhere classified.

This NACE division is composed of four groups:

- office administrative and support activities (Group82.1);
- activities of call centres (Group82.2);
- organisation of conventions and trade shows (Group82.3);
- business support service activities n.e.c. (Group82.9).

The provision of operating staff to carry out the complete operations of a business is excluded from the activities covered in this article, as is the provision of a single (only one) particular aspect of these operations. Also excluded from this division are the printing of documents (offset printing, quick printing and so on) and pre-press services (which are part of the [printing and reproduction of recorded media](#) , Division18), the manufacture of soft drinks and production of mineral water (which are part of the [manufacture of beverages](#) , Division11) and packaging activities incidental to transport (which are part of [warehousing and support activities for transportation](#) , Division52).

Table 4b: Key indicators, other manufacturing (NACE Division32), 2009 - Source: Eurostat (sbs_na_ind_r2)

Main statistical findings

Structural profile

The EU-27's other manufacturing sector (Division32) employed 800 thousand persons in 2009, equivalent to 0.6% of the total number of persons employed in the non-financial business economy (Sections B to J and L to N and Division95) and 2.6% of the manufacturing (Section C) workforce. The other manufacturing sector's value added was EUR37016 million which was 0.7% of the non-financial business economy total and 2.7% of the manufacturing total.

The apparent labour productivity of the EU-27's other manufacturing sector in 2009 was EUR46 thousand per person employed, the same as the manufacturing average and above the non-financial business economy average of EUR41.6 thousand per person employed. Despite this relatively high apparent labour productivity, average personnel costs within the EU-27's other manufacturing sector were EUR30.0 thousand per employee, below the EUR34.5 thousand per employee average in manufacturing and the same as the non-financial business economy average.

The combination of the previous two indicators resulted in a wage-adjusted labour productivity ratio for the EU-27's other manufacturing sector that was 141.7% in 2009, slightly above the non-financial business economy average (138.8%) and well above the manufacturing average (132.1%). The gross operating rate was particularly high: as the gross operating surplus was equivalent to 14.3% of turnover within the EU-27's other manufacturing sector in 2009, just over double the manufacturing average (7.0%) and about 1.5 times as high as the non-financial business economy average (9.7%). This was the second highest level of profitability (using this measure) among the manufacturing NACE divisions, with only pharmaceuticals manufacturing (Division21) recording a higher value.

Sectoral analysis

The other manufacturing sector contains six subsectors at the NACE group level. Within the EU-27 the largest of these was the manufacture of medical and dental instruments and supplies (Group32.5), which accounted for close to three fifths (56.8%) of sectoral employment and nearly two thirds (65.0%) of sectoral value added in 2009. The next largest subsector was manufacturing not elsewhere classified (Group32.9) which is a miscellaneous heading covering the production of a heterogeneous range of products, including, for example, pencils, umbrellas, candles and coffins; this subsector contributed 13.2% of sectoral value added in 2009 and employed

nearly one fifth (19.9%) of the other manufacturing workforce. Ranked on their contribution to the sector's total employment the remaining subsectors concerned the manufacture of: jewellery, bijouterie and related articles (Group32.1), games and toys (Group32.4), sports goods (Group32.3) and musical instruments (Group32.2).

In terms of productivity and average personnel costs the largest subsector, namely medical and dental instruments and supplies manufacturing, stood out from the other subsectors; note that some of these indicators are not available for games and toys manufacturing. The EU-27's medical and dental instruments and supplies manufacturing subsector was the only one within the other manufacturing sector to record apparent labour productivity, average personnel costs and wage-adjusted labour productivity ratios above the manufacturing average in 2009.

For the gross operating rate, data for the EU-27 is only available for four of the six other manufacturing NACE groups. The two largest subsectors recorded gross operating rates above the non-financial business economy average (9.7%) in 2009, 16.6% for medical and dental instruments and supplies manufacturing and 10.7% for the miscellaneous activity of manufacturing not elsewhere classified. The lowest gross operating rate among the four subsectors for which data are available was 6.3% for sports goods manufacturing, which was the only one of the four subsectors with a gross operating rate below the manufacturing average (7.0%) in 2009.

Country analysis

The German share of EU-27 value added in the other manufacturing sector was 29.0% in 2009, a share that rose to 42.4% for the relatively small activity of musical instruments manufacturing. Germany's share of EU-27 value added was more than double the shares of the next largest Member States, namely Italy (12.0%), France (11.9%) and the United Kingdom (11.3%). Germany had the highest value added of any Member State for four of the other manufacturing subsectors, with Italy recording the highest level of output for both the manufacture of sports goods and jewellery, bijouterie and related articles.

The relative importance of the other manufacturing sector was highest in Ireland where this sector contributed 3.3% of non-financial business economy value added in 2009. Irish specialisation was far greater than in any other Member State: Denmark was the most specialised Member State, as the other manufacturing sector contributed 0.9% of non-financial business economy value added. The least specialised Member States were Cyprus, Romania and Luxembourg as the other manufacturing sector contributed 0.2% or less to their non-financial business economy value added in 2009.

In value added terms, the most specialised Member States for jewellery, bijouterie and related articles manufacturing were Italy and Cyprus; no recent data is available for Greece which traditionally is also specialised in this activity. Austria, the Czech Republic and Germany were the most specialised countries for musical instruments manufacturing. Austria was also specialised in sports goods manufacturing (including winter sports equipment); data for 2008 shows that Estonia was also strongly specialised in this subsector. The Czech Republic and Austria were the most specialised for games and toys manufacturing, although it should be noted that no recent data are available for several Member States including Denmark and Malta (both of which are known to be traditionally specialised in games and toys manufacturing). Ireland was, by far, the most specialised Member State for medical and dental instruments and supplies manufacturing, which was largely responsible for Ireland's position as the most specialised Member State in the other manufacturing sector as a whole. The Czech Republic, Estonia and Lithuania were the most specialised Member States for the miscellaneous subsector of manufacturing not elsewhere classified.

These various specialisations are reflected to some extent in the derived indicators shown in Table 4b. In particular, Ireland's specialisation in the medical and dental instruments and supplies manufacturing subsector resulted in Ireland (270.8%) recording the highest wage-adjusted labour productivity ratio for the other manufacturing sector. The other Member States recorded wage-adjusted labour productivity ratios ranging from 110.8% in Italy to 193.1% in Denmark (2008 data). Most Member States recorded a wage-adjusted labour productivity ratio in this sector that was below their national non-financial business economy average, the exceptions being Ireland, Denmark (2008 data), Lithuania, the United Kingdom and Estonia. In contrast, the gross operating rates for the other manufacturing sector were high, as Austria and Cyprus were the only Member States (with data available) to record lower rates for the other manufacturing sector than for their non-financial business economy as a whole. Ireland, Denmark (2008 data) and the United Kingdom all recorded gross operating rates above 20% in 2009.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the other manufacturing sector in the EU, as covered by NACE Rev.2 Division32. This division includes the manufacture of a variety of goods not covered in other parts of manufacturing. As this is a residual division, production processes, input materials and the use of the produced goods can vary widely.

The manufacture of jewellery includes the striking of coins, the production of worked pearls, precious and semi-precious stones (including industrial quality and synthetic stones), diamonds, jewellery (including imitation), goldsmiths' articles, technical or laboratory articles of precious metal (except instruments) and the engraving of personal products.

The manufacture of musical instruments includes stringed, wind, percussion, keyboard and electronic instruments, as well as musical boxes, whistles and other mouth-blown sound signalling instruments.

The manufacture of sports goods includes the manufacture of sporting and athletic goods except apparel and footwear.

The manufacture of games and toys includes the manufacture of dolls, toy animals, toys, and games (including electronic), hobby kits, children's vehicles (except metal bicycles and tricycles), so-called scale models, train and construction sets, puzzles and so on.

The manufacture of medical and dental instruments and supplies includes laboratory apparatus, surgical and medical instruments, surgical appliances and supplies, dental equipment and supplies, orthodontic goods, dentures, and orthodontic appliances.

Manufacturing not elsewhere classified includes the manufacture of brooms and brushes, protective safety equipment, pens and pencils, hand-operated devices for printing, globes, umbrellas, walking sticks, buttons and other fasteners, cigarette lighters, candles, artificial flowers, tailors' dummies, burial coffins and so on, as well as articles of personal use (such as smoking pipes or combs).

This NACE division is composed of six groups:

- the manufacture of jewellery, bijouterie and related articles (Group32.1);
- the manufacture of musical instruments (Group32.2);
- the manufacture of sports goods (Group32.3);
- the manufacture of games and toys (Group32.4);
- the manufacture of medical and dental instruments and supplies (Group32.5);
- manufacturing n.e.c. (Group32.9).

The activities covered by this article exclude the manufacture of saddlery, harnesses, whips, riding crops (which form part of the [manufacture of leather and related products](#) , Division15), sporting weapons and ammunition and metal weights used for weightlifting (which are included within the [manufacture of fabricated metal products](#) , Division25), video game consoles, record players and the like (included within the [manufacture of computer, electronic and optical products](#) , Division26), as well as sports vehicles other than toboggans and the like (which are classified as part of the [manufacture of motor vehicles, trailers and semi-trailers](#) and the

[manufacture of other transport equipment](#) , Divisions29 and 30).

Table 4b: Key indicators, other mining and quarrying (NACE Division08), 2009- Source: Eurostat (sbs_na_ind_r2)

Main statistical findings

Structural profile

The EU-27's other mining and quarrying sector (Division08) comprised 18thousand enterprises in 2009, employed 221thousand persons, and generated EUR11719 million of value added. As such, this sector contributed 0.2% of the EU-27's non-financial business economy (Sections B to J and L to N and Division95) employment and value added, while its contribution to mining and quarrying (SectionB) was 34.6% of the workforce and 16.3% of value added.

Apparent labour productivity in the EU-27's other mining and quarrying sector was EUR53 thousand per person employed in 2009, somewhat above the non-financial business economy average of EUR41.6 thousand per person employed but equivalent to less than half the mining and quarrying average of EUR112 thousand per person employed. The average personnel costs within the EU-27's other mining and quarrying sector were EUR31.0 thousand per employee in 2009, which was between the average for the non-financial business economy (EUR30.0 thousand per employee) and the average for mining and quarrying (EUR34.0 thousand per employee).

The wage-adjusted labour productivity ratio combines the two previous indicators and shows that value added per person employed was equivalent to 170.8% of average personnel costs per employee in the EU-27's other mining and quarrying sector in 2009. As such, the value for this sector was again closer to the non-financial business economy average (138.8%) than to the mining and quarrying average (321.4%). A broadly similar situation was observed for the gross operating rate, which was 15.5% for other mining and quarrying, between the non-financial business economy average (9.7%) and the mining and quarrying average (26.6%).

Sectoral analysis

Around six out of every seven enterprises within the EU-27's other mining and quarrying sector were classified under the quarrying of stone, sand and clay (Group08.1), while the remainder were classified to mining and quarrying not elsewhere classified (Group08.2). In output and employment terms the relative importance of quarrying of stone, sand and clay was slightly less, with 81.1% of sectoral value added and 83.6% of sectoral employment – see Figure1.

Through its size, the relatively large subsector for quarrying of stone, sand and clay dominates the other

mining and quarrying sector and therefore the values for many derived indicators for this subsector are generally close to the sectoral average. Apparent labour productivity for the quarrying of stone, sand and clay was EUR51 thousand per person employed, whereas for mining and quarrying not elsewhere classified it reached EUR60 thousand per employee. In a similar manner, the gross operating rate for mining and quarrying not elsewhere classified (17.5%) was somewhat higher than that for the quarrying of stone, sand and clay (15.1%); both of these rates were above the non-financial business economy average (9.7%) in 2009, but below the mining and quarrying average (26.6%).

Country analysis

Germany recorded the highest share (18.3%) of EU-27 value added within the other mining and quarrying sector in 2009, followed by France (17.6%) and Spain (12.1%). Germany's position as the largest Member State in the sector was reinforced by having the largest value added terms in the mining and quarrying not elsewhere classified subsector (21.5% of EU-27 value added), whereas France had the largest share (20.2%) for the quarrying of stone, sand and clay subsector.

The same three Member States (Germany, France and Spain) had the largest workforces in the other mining and quarrying sector, although their shares of the EU-27 total were all smaller in employment terms – ranging from 14.0% in Germany to 10.5% in Spain – than they were in value added terms; note that the French data relate to the number of employees, rather than persons employed. The difference between shares of value added and employment can be explained to some extent by the large Polish share of the EU-27 workforce, which reached 10.2% in 2009, which was approximately double the Polish share of EU-27 value added in this sector.

In value added terms the most specialised Member State in this sector in 2009 was Latvia, as 0.8% of Latvian non-financial business economy value added was generated in the other mining and quarrying sector, more than three and a half times the EU-27 average (0.2%). The only other Member States where this sector accounted for 0.5% of non-financial business economy value added in 2009 was Cyprus.

The highest wage-adjusted labour productivity ratios recorded within the other mining and quarrying sector in 2009 were in the Netherlands, Cyprus, Hungary and Latvia, all in excess of 220%. Ireland was the only Member State where the wage-adjusted labour productivity ratio was below 100%, as the apparent labour productivity in Ireland was just 91.5% of the average personnel costs – see Table4b.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the other mining and quarrying sector in the EU, covering NACE Rev.2 Division08. This division includes extraction from mines or quarries as well as dredging of alluvial deposits, rock crushing and the use of salt marshes. These products are used most notably in construction (for example, sands and stones), chemicals and materials manufacturing (for example, clay, gypsum and calcium).

Other mining and quarrying not elsewhere classified includes, for example, the mining and quarrying of abrasive materials, asbestos, natural graphite, steatite (talc), feldspar, natural asphalt, gemstones, quartz and mica.

This NACE division is composed of two groups:

- the quarrying of stone, sand and clay (Group 08.1);

- [mining and quarrying not elsewhere classified \(Group 08.9\)](#).

This division does not include processing (except crushing, grinding, cutting, cleaning, drying, sorting and mixing) of the minerals extracted.

Main statistical findings

Structural profile

There were 508 thousand enterprises classified to the other professional, scientific and technical activities sector (Division 74) in the EU-27 in 2009. These enterprises employed 930 thousand persons, approximately 0.7% of the total number of persons employed in the non-financial business economy (Sections B to J and L to N and Division 95) and 8.5% of the workforce for professional, scientific and technical activities (Section M). They generated EUR 33000 million of value added which was approximately 0.6% of the non-financial business economy total and 6.3% of the professional, scientific and technical activities total.

The apparent labour productivity of the EU-27's other professional, scientific and technical activities sector in 2009 was EUR 36 thousand per person employed, below the non-financial business economy average of EUR 41.6 thousand per person employed and the professional, scientific and technical activities average of EUR 47 thousand per person employed. Average personnel costs within the EU-27's other professional, scientific and technical activities sector were EUR 30.7 thousand per employee, which was marginally higher than the EUR 30.0 thousand per employee average for the non-financial business economy but substantially below the EUR 40.5 thousand per employee average for professional, scientific and technical activities. The impact of relatively low apparent labour productivity was to pull down the wage-adjusted labour productivity ratio for the EU-27's other professional, scientific and technical activities. In 2009, this ratio stood at 115.6%, which was far below the non-financial business economy average (138.8%), although broadly in line with average for all professional, scientific and technical activities (117.0%).

The gross operating rate for the EU-27's other professional, scientific and technical activities sector in 2009 showed that this sector's gross operating surplus was 24.4% of turnover. This level of operating profitability (using this measure) was two and a half times as high as the non-financial business economy average (9.7%) and was also higher than the average for all professional, scientific and technical activities (17.8%).

Sectoral analysis

Around half of all the enterprises within the EU-27's other professional, scientific and technical activities sector in 2009 were classified to the miscellaneous subsector of other professional, scientific and technical activities not elsewhere classified (Group 74.9). This subsector includes, for example, business and patent brokerages, bill auditing and freight rate information, weather forecasting and environmental consulting. The other professional,

scientific and technical activities not elsewhere classified subsector contributed 61.2% of sectoral value added and employed more than half (55.2%) of the sectoral workforce and had the highest apparent labour productivity (EUR39 thousand per person employed) and the highest average personnel costs (EUR33.3 thousand per employee) among the four subsectors. The balance between apparent labour productivity and average personnel costs resulted in a wage-adjusted labour productivity ratio (118.0%) for the other professional, scientific and technical activities not elsewhere classified subsector that was just above the sectoral average (115.6%) and in line with the average for all professional, scientific and technical activities (117.0%). This subsector's gross operating rate (24.0%) was just below the sectoral average (24.4%), but well above the average for all professional, scientific and technical activities (17.8%).

Within the EU-27 the three remaining subsectors within the other professional, scientific and technical activities sector followed a similar rank from largest to smallest regardless of which measure was used to determine their relative size (numbers of enterprises, employment or value added): the smallest subsector was translation and interpretation activities (Group74.3), followed by photographic activities (Group74.2), while the largest was specialised design activities (Group74.1). The translation and interpretation activities subsector had the lowest apparent labour productivity within the other professional, scientific and technical activities sector while the photographic activities subsector had the lowest average personnel costs (2008 data) – see Table 2b. Due to its particularly low average personnel costs, the photographic activities subsector also recorded the highest wage-adjusted labour productivity ratio (135.1%, 2008 data) among the four subsectors. In contrast, the wage-adjusted labour productivity ratio for the translation and interpretation activities subsector was pulled down by its low apparent labour productivity and was just 106.5%. All four subsectors recorded relatively high gross operating rates, peaking at 30.1% for translation and interpretation activities, which ranked just outside the top ten among all non-financial business economy NACE groups in 2009.

Country analysis

One quarter (25.9%) of the value added generated in the EU-27's other professional, scientific and technical activities sector in 2009 was accounted for by the United Kingdom, a share that rose to 27.0% for the miscellaneous subsector of other professional, scientific and technical activities not elsewhere classified and 32.0% for specialised design activities. Germany had the highest value added in the other two subsectors. The high contribution of the United Kingdom to the EU-27 total was reflected by the fact that it was the most specialised Member State, in value added terms, as 1.0% of non-financial business economy value added in the United Kingdom came from other professional, scientific and technical activities in 2009, just ahead of a 0.9% share for Italy. The least specialised Member State in 2009 was Romania where this sector contributed 0.2% of non-financial business economy value added.

Wage-adjusted labour productivity ratios for the other professional, scientific and technical activities sector failed to reach 100% in eight Member States in 2009, a frequency that was only surpassed by two other NACE divisions within the non-financial business economy. In contrast, the wage-adjusted labour productivity ratio for the other professional, scientific and technical activities sector was above the non-financial business economy average for three Member States in 2009, most notably in Slovakia, but also in the United Kingdom and Sweden.

The relatively high gross operating rate observed for the other professional, scientific and technical activities sector in the EU-27 in 2009 was also evident in nearly all Member States, as Ireland was the only one where the gross operating rate was below the average rate for its non-financial business economy. Germany recorded the highest rate (34.3%) among the Member States in 2009, followed by Italy (31.0%) and the United Kingdom (29.7%).

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the other professional, scientific and technical activities sector in the EU, as covered by NACE Rev.2 Division74. This division includes the provision of professional scientific and technical services not elsewhere classified, therefore not in Divisions69 to 73.

Specialised design activities include fashion design (for example, related to textiles, jewellery, furniture, personal or household goods), industrial design, graphic design and interior decoration.

Photographic activities include commercial and consumer photograph production, for example, for passports, schools, weddings, publishers, fashion, real estate and tourism. Also included is aerial photography, videotaping of events, film processing and the activities of photojournalists.

Other professional, scientific and technical activities not elsewhere classified include a great variety of service activities generally delivered to commercial clients. This includes those activities for which more advanced professional, scientific and technical skill levels are required, but does not include ongoing, routine business functions that are generally of short duration – these are generally classified to Divisions77 to 82.

This NACE division is composed of four groups:

- specialised design activities (Group74.1);
- photographic activities (Group74.2);
- translation and interpretation activities (Group74.3);
- other professional, scientific and technical activities n.e.c. (Group74.9).

The information presented in this article does not cover architectural and engineering design (part of [architectural and engineering activities; technical testing and analysis](#) , Division71). The coverage of this article also excludes processing motion picture film related to motion picture and television (part of [motion picture, video and television programme production, sound recording and music publishing activities](#) , Division59) and the operation of coin operated (self-service) photo machines (classified as part of other personal service activities, Division96).

Pesticide, paint, soap and fibre production statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). The present article covers the production of pesticide, paint, soap and fibre, which is part of the [fuel and chemicals production](#) sector. The activities covered in this article correspond to five different [NACE Rev 1.1](#) groups, which cover the manufacture of:

- pesticides and other agro-chemical products (NACE Group 24.2);
- paints and printing inks (NACE Group 24.3), which includes paints, varnishes, enamels, lacquers, solvents, thinners, varnish removers and printing inks;
- soaps, detergents and toiletries (NACE Group 24.5), which includes washing and cleaning products, perfumes, toiletries and cosmetics;
- other chemical products (NACE Group 24.6), a residual grouping that includes the manufacture of photographic materials, explosives, glues and essential oils, as well as intermediate inputs for other manufacturing processes;
- man-made fibres (NACE Group 24.7).

	Enterprises (thousand)	Turnover (EUR million)	Value added (EUR million)	Persons employed (thousand)	Share in total (%)

Table 3: Manufacture of miscellaneous chemical products (NACE Groups 24.2, 24.3, 24.5 to 24.7). Expenditure, productivity and profitability, EU-27, 2006

The pesticide, paint, soap and fibre production sector (NACE Groups 24.2, 24.3, 24.5, 24.6 and 24.7) comprised a total of a little over 20.5 thousand enterprises across the EU-27 in 2005 that employed 708.8 thousand persons in 2006. These enterprises generated EUR 197.3 billion of turnover of which EUR 51.4 billion was left as value added in 2006, a little less than a quarter (22.6% in 2005) of the total value added generated across fuel processing and chemicals manufacturing in the EU-27.

Manufacture of pesticides and other agro-chemical products

There were just over 600 enterprises across the EU-27 for which the manufacture of pesticides and other agro-chemical products was their main activity in 2005. These enterprises employed 29.1 thousand people, accounting for 1.4% of the workforce across fuel processing and chemicals manufacturing in 2006. The sector generated value added of EUR 2.7 billion in 2006, representing a slightly lower share (1.2% in 2005) of the value added generated within fuel processing and chemicals manufacturing activities.

Among the Member States, the main producer of pesticides and other agro-chemical products was Germany, accounting for over one third (37.6%) of the value added generated in the EU-27 and employing a little less than one quarter (23.5%) of the total workforce. In value added terms, Germany was also the Member State

most specialised in this activity.

After a period of annual fluctuations, there was a clear downward trend in the production index of pesticides and other agro-chemical products across the EU-27 between 2001 and 2007 (an [average](#) decline of 2.5% per year). In large part, this decline may be linked to improved incentives to farm in an environmentally sensitive way since the so-called Agenda 2000 reform of the [Common agricultural policy \(CAP\)](#) .

EU-27 [tangible investment](#) in the pesticides and other agro-chemical products manufacturing sector was EUR 0.3 billion in 2006, a relatively small 0.9% share of total tangible investment within fuel processing and chemical manufacturing. Relative to value added generated across the sector, this was the equivalent of an investment rate of 10.5%, which was notably less than the rate of 14.4% for the whole of fuel processing and chemicals manufacturing in 2005.

[Personnel costs](#) accounted for 14.6% of operating expenditure in this sector in 2006, a little more than the average across fuel processing and chemicals manufacturing (11.7% in 2005). There was almost no difference in average personnel costs, however, which were EUR 55.0 thousand per employee for the EU-27's pesticides and other agro-chemical products manufacturing sector. The apparent [labour productivity](#) of those working in this sector was EUR 93.3 thousand per person employed, slightly more than 10% below the average for fuel processing and chemicals manufacturing in 2005. The wage adjusted labour productivity ratio of the pesticides and other agro-chemical products manufacturing sector was 169.6% in 2006.

Manufacture of paints and printing inks

Paint and printing inks manufacturing was the principal activity of 4.5 thousand enterprises across the EU-27 in 2006, providing employment for and estimated 174.0 thousand people, the equivalent of 8.4% of the fuel processing and chemicals manufacturing workforce. The paint and printing inks manufacturing sector generated EUR 12.0 billion of value added in the EU-27 in 2006, of which three tenths (29.9%) came from these activities in Germany and a similar, combined, proportion from the United Kingdom (15.4%) and Italy (13.8%). Although there was moderate specialisation in this activity in Germany, specialisation was stronger in both Estonia and Slovenia, where the value added generated by their respective paints and printing inks manufacturing sectors made about twice the contribution to their national [non-financial business economies](#) as was the average across the EU-27.

During the period between 1997 and 2007, there were three relatively distinct developments in the production index of paints and printing inks; in the period between 2000 and 2005, there was little change in EU-27 output, either side of which there was relatively strong growth. Over the ten year period as a whole, growth in [output](#) averaged 2.0% per year.

EU-27 tangible investment in the paint and printing inks manufacturing sector was EUR 1.1 billion in 2006. Compared with the value added generated by this sector, this represented a relatively low [investment rate](#) of 9.0% even when compared with the average rate across fuel processing and chemicals manufacturing (14.4% in 2005). In contrast, personnel costs represented a relatively high proportion of operating expenditure (18.6% compared with 11.7% in 2005 for fuel processing and chemicals manufacturing), despite average personnel costs in the paints and printing inks sector (EUR 43400 per employee) being relatively low.

The apparent labour productivity of those working in the EU-27's paints and printing inks manufacturing sector was EUR 69.1 thousand per person employed in 2006, about EUR 36.0 thousand less per person than the average level across fuel processing and chemicals manufacturing in 2005. Even after taking into account relatively lower average personnel costs, the wage adjusted labour productivity ratio of the paints and printing inks sector (159.3%) remained some way beneath the average ratio for fuel processing and chemicals manufacturing (194.9% in 2005), although it was still just above the average ratio across the non-financial business economy.

Manufacture of soaps, detergents and toiletries

There were 8.3 thousand enterprises across the EU-27 for which the manufacture of soaps, detergents and toiletries was their main activity in 2006. These enterprises employed 266.4 thousand persons, accounting for 12.9% of the total workforce in fuel processing and chemicals manufacturing. In relative terms, the sector was

rather larger in terms of employment than in terms of the value added generated (EUR 17.8 billion).

The manufacture of perfumes and toilet preparations (NACE Class 24.52) in the EU-27 was slightly larger than the manufacture of soap and detergents (NACE Class 24.51), generating EUR 1.2 billion more value added in 2006. Among almost all of the Member States, however, the soap and detergents subsector was much the larger of the two. The overall picture for the EU-27 was shaped largely by the size of the perfumes and toiletries manufacturing sector in France; it accounted for 40.9% of EU-27 value added compared with a share of only 10.9% within the soap and detergents manufacturing subsector. Poland and France were the only two Member States that were significantly relatively specialised in soaps, detergent and toiletries manufacturing in the EU-27, the contribution of value added to their respective non-financial business economies being about twice the average across the EU-27

There was relatively little change in the EU-27

production index of the soaps, detergents and toiletries manufacturing sector between 1997 and 2001. However, there then followed a period of accelerated growth through to 2007 (at an average rate of 3.3% per year). These two distinct periods reflected a relative balance between the output growth of perfumes and toilet preparations manufacturing and output declines for soap and detergent manufacturing up to 2001, followed by relatively strong growth in the output of both subsectors through to 2007.

Tangible investment in the soaps, detergents and toiletries sector of the EU-27 was EUR 2.1 billion in 2006, accounting for 6.4% of total tangible investment across fuel processing and chemicals manufacturing, rather less than its relative share of value added (8.2% in 2005). This explains the relatively low investment rate of 12.1% in 2006. In contrast, personnel costs represented a relatively high proportion of operating expenditure (16.5% compared with 11.7% in 2005 across fuel processing and chemicals manufacturing), despite average personnel costs for the soaps, detergents and toiletries sector (EUR 40800 per employee) being about one quarter (24.5%) lower.

The apparent labour productivity of those working in the soaps, detergents and toiletries sector in the EU-27 was EUR 66.8 thousand per person employed in 2006, about a third less than the average productivity of those working across fuel processing and chemicals manufacturing in 2005. This relative difference was narrowed somewhat when adjusting productivity for wage differences; the wage adjusted labour productivity ratio was 163.6% in 2006, compared with an average of 194.9% for fuel processing and chemicals manufacturing in 2005.

Manufacture of other chemical products

The manufacture of other chemical products, such as photographic materials, explosives, glues and essential oils was the principal activity of about 6.8 thousand enterprises across the EU-27 in 2006. This grouping of activities provided employment for 195.6 thousand people across the EU-27, a little less than one tenth (9.5%) of the total fuel processing and chemical manufacturing workforce. The sector generated turnover of EUR 57.3 billion in 2006, of which a little over one quarter was left as value added (EUR 16.2 billion).

A clear majority of both the value added generated in the sector (62.1%) and the number of persons employed (59.8%) came from the manufacturing subsector of other chemical products not elsewhere classified (NACE Class 24.66), such as the manufacture of writing inks, lubricating preparations, additives and anti-freezing preparations.

The other chemical products manufacturing sector in Germany generated about one quarter (25.5%) of the value added generated by this sector across the EU-27 in 2006, more than any other Member State. However, the only Member State that was highly specialised in this group of manufacturing activities was Belgium, the contribution of value added from this sector to its non-financial business economy being almost four times the EU-27 average.

The overall rise in the EU-27 production index of other chemicals manufacturing during the period between 1997 and 2007 was largely determined by the strong growth in the output of other chemical products not elsewhere classified (NACE Class 24.66) in the four years after 2003 (an overall increase of 21.4%).

Tangible investment in the other chemicals manufacturing sector was EUR 2.1 billion in 2006, representing

6.2% of total tangible investment across fuel processing and chemicals manufacturing in the EU-27. This represented a slightly lower proportion than that of the sector's contribution to value added, which was reflected in a lower investment rate (12.7%) in 2006 than across fuel processing and chemicals manufacturing as a whole in 2005. Personnel costs represented a relatively high proportion (17.6%) of operating expenditure in the EU-27's other chemicals manufacturing sector in 2006 when compared with fuel processing and chemicals manufacturing (11.7% in 2005), despite average personnel costs being about 15% lower.

The apparent labour productivity of those working across the EU-27 in the other chemical products manufacturing sector was EUR 82.8 thousand per person employed in 2006, about a fifth lower than the average for fuel processing and chemical manufacturing in 2005. The difference in productivity was narrowed when taking the lower average personnel costs of the sector into account; the average wage adjusted labour productivity ratio for the other chemical products manufacturing sector of the EU-27 was 177.6% in 2006.

Manufacture of man-made fibres

The man-made fibres manufacturing sector in the EU-27

only comprised 355 enterprises in 2006. This relatively small sector employed 43.7 thousand persons, representing 2.1% of all those working throughout fuel processing and chemicals manufacturing in the EU-27. This sector's value added was EUR 2.6 billion in 2006, and its contribution to the total for fuel processing and chemicals manufacturing in value added terms was about half its contribution in employment terms.

Among the Member States, by far the largest man-made fibres manufacturing sector was in Germany; it contributed almost one third (33.1%) of the EU-27's total value added. However, Austria was clearly the Member State most specialised in this manufacturing activity, the contribution of the value added of the man-made fibres manufacturing sector to its non-financial business economy being about four and a half times the EU-27 average.

There was a distinct downward trend in the EU-27 [production index](#) for man-made fibres in the ten year period through until 2007, although there were some temporary upturns (such as in 2000 and 2004). Between 1997 and 2007, the average rate of decline in the output of man-made fibres manufacturing across the EU-27 was 3.2% per year, with notably faster rates of decline in Italy (an average -6.1% per year), the United Kingdom (-7.3%) and Spain (-8.7%). This downward trend contrasted sharply with the increasing trend of output observed for the EU-27's production index for fuel processing and chemicals manufacturing over the same period.

Tangible investment in the EU-27's man-made fibres manufacturing sector was EUR 0.5 billion in 2005, the equivalent of 1.5% of the total tangible investment across fuel processing and chemicals manufacturing. Although small, this share represented slightly more than the equivalent share in terms of value added, resulting in an investment rate (17.4%) for man-made fibres manufacturing sector that was higher than the average (14.4%) for the whole of fuel processing and chemicals manufacturing in 2005.

Although average personnel costs (EUR 40.9 thousand per employee in 2006) in the EU-27's man-made fibres manufacturing sector were low, about a quarter less than the average for fuel processing and chemicals manufacturing, the share of personnel costs in operating expenditure was notably higher (15.4% in 2006 – down from 19.0% in 2005 – compared with 11.7% in 2005 for fuel processing and chemicals manufacturing as a whole).

The apparent labour productivity of those working in the man-made fibres manufacturing sector was EUR 60.4 thousand per person employed in 2006, about two fifths (42.7%) less than the average value added generated per person employed across fuel processing and chemicals manufacturing in the EU-27 in 2005. The value added generated per person employed in the sector was a little less than 50% higher than average personnel costs in 2006, which can be seen from a wage-adjusted labour productivity ratio of (147.9%). considerably less than the ratio for the whole of fuel processing and chemicals manufacturing (194.9% in 2005).

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include [short-term statistics \(STS\)](#) and the [PRODCOM](#) statistics on the production of manufactured goods.

Context

Enterprises in the fuel processing and chemicals sector operate within a highly regulated framework that extends from the supply of the raw materials, through their processing to the treatment of waste. The Registration, Evaluation and Authorisation of Chemical substances (the so-called [REACH](#) Regulation) came into force on 1 July 2007, with the main aims of improving the protection of human health and the environment from risks posed by chemicals. The first list of 15 chemicals to undergo scrutiny was published by the [European Chemicals Agency](#) in October 2008. A new [European Parliament](#) and [Council Regulation](#) on the classification, labelling and packaging of chemical substances and mixtures (CLP) was adopted in December 2008, in order to align the labelling and description of hazards around the world. The CLP Regulation entered into force on 20 January 2009, with the deadline for substance classification according to the new rules by 1 December 2010 and for mixtures by 1 June 2015.

The fuel processing and chemicals sector faces a number of key challenges; these are energy and raw materials supply, climate change and barriers to market entry in emerging countries. Against this background, the High Level Group on the Competitiveness of the European Chemicals Industry, which was first proposed by the [European Commission](#) in June 2007 ([COM\(2007\) 418](#)), released its final strategy report in February 2009. The strategies focus on more innovation and research (see the importance of this in the article called [Pharmaceuticals production statistics - NACE Rev. 1.1](#)), the responsible use of resources and a level playing field for sourcing energy and raw materials, and a drive to open world markets.

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). The present article covers the manufacture of petrochemicals and basic chemicals, corresponding to [NACE Rev 1.1](#) Group 24.1, which is part of the [fuel and chemicals production](#) sector. The activities covered in this article are the manufacture of:

- petrochemicals;
- industrial gases;
- dyes;
- pigments;
- fertilisers;
- primary forms of plastics and synthetic rubber.

	Enterprises (thousand)	Turnover (EUR million)	Value added (EUR million)	Persons employed (thousand)	Share in total (%)	
					Value added	Persons employed

Table 4: Manufacture of basic chemicals (NACE Group 24.1). Expenditure, productivity and profitability, EU-27, 2006 (1)

The manufacture of basic chemicals (NACE Group 24.1) was the principal activity of about 8.5 thousand enterprises across the EU-27 in 2006. These enterprises employed an estimated 562.0 thousand people in 2006, a little over one quarter (27.2%) of the fuel processing and chemicals workforce. The basic chemicals manufacturing sector generated a turnover of EUR 322.9 billion in 2006, about one fifth (EUR 65.0 billion) of which was left as value added.

The manufacture of other organic basic chemicals (NACE Class 24.14) such as hydrocarbons, organic compounds with nitrogen functions and organo-sulphur compounds generated EUR 28.3 billion of value added in 2006 in the EU-27, accounting for a little more than two fifths (43.5%) of the value added across basic chemicals manufacturing. The second largest activity within the sector was the manufacture of plastics in primary forms (NACE Class 24.16), the EUR 20.3 billion of value added generated corresponding to a little less than one third (31.2%) of sectoral value added in 2006. Of the remaining activities, the manufacture of other inorganic basic chemicals (NACE Class 24.13) such as carbonates, metallic halogenates and inorganic acids and compounds generated EUR 5.8 billion of value added and that of industrial gases (NACE Class 24.11) a further EUR 4.2 billion of value added. The combined value added of the manufacture of dyes and pigments (NACE Class 24.12), fertilisers and nitrogen compounds (NACE Class 24.15) and the manufacture of synthetic rubber in primary forms (NACE Class 24.17) accounted for about one tenth (9.8%) of the value added generated across the EU-27's basic chemicals manufacturing sector in 2006.

The basic chemicals manufacturing sector in Germany was by far the largest among the Member States, alone generating 29.0% of the value added generated by this sector across the EU-27. However, Ireland was the Member State by far the most specialised in the manufacture of basic chemicals, the EUR 8.6 billion of value added generated in 2006 contributing 9.4% of the value added generated across its non-financial business economy, which was a little more than eight times the average contribution among Member States. The only other Member State⁹⁷ that showed relatively strong specialisation in this activity in 2006 was Belgium.

The production index for basic chemicals manufacturing in the EU-27 rose continuously during the ten year period through until 2007, at an average 3.3% per year. Output growth was strongest in the period before 2002, after which it slowed considerably before picking up again in 2005. Growth was particularly strong in

⁹⁷Data for the Netherlands are unavailable for 2005 and 2006, although figures for earlier years also point to a similar level of specialisation in this activity as in Belgium.

Ireland (an average 12.6% per year), where output almost quadrupled in the period between 1997 and 2003 before falling back to a more sustained level.

There were relatively steady rises in the output of both other organic basic chemicals and industrial gases during the ten years through until 2007 across the EU-27. In contrast, there was relatively little difference in the output levels of fertilisers and nitrogen compounds, nor dyes and pigments in 2007 (when compared with levels in 1997), although there were regular fluctuations in the intervening years. However, a fluctuating but downward trend was observed for the output of synthetic rubber in primary forms, particularly in the period after 2003.

Expenditure and productivity

Tangible investment across the EU-27 in the basic chemicals manufacturing sector was EUR 12.1 billion in 2006, a little over one third (36.3%) of all tangible investment across fuel processing and chemicals manufacturing. The resulting investment rate was 18.7%, slightly higher than the non-financial business economy average (18.4%).

The operating expenditure structure of the basic chemicals manufacturing sector in the EU-27 was similar to the average across the whole of fuel processing and chemicals manufacturing in 2005. Personnel costs accounted for a little more than one tenth (10.5%) of operating expenditure in the sector in 2006.

The average amount of value added generated by each person employed across the EU-27 in basic chemicals manufacturing was EUR 115.6 thousand in 2006, about a tenth higher than the average (in 2005) across fuel processing and chemicals manufacturing. This relative productivity advantage was maintained, even when adjusting productivity for wages, as average **personnel costs** in the sector (EUR 55.1 thousand per person employed in 2006) were very similar to the average for the whole of fuel processing and chemicals manufacturing. The wage adjusted **labour productivity** ratio of the basic chemicals manufacturing sector within the EU-27 was 209.7% in 2006, which was bolstered by the high ratio (281.0%) recorded for the other organic basic chemicals subsector (NACE Class 24.14), the largest activity in terms of value added. Of the other activities, the wage adjusted labour productivity ratio (211.9%) of the industrial gases subsector (NACE Class 24.11) was the only other to equal or surpass the ratio for the sector as a whole. All the other five subsectors at the NACE class level recorded wage adjusted labour productivity ratios in the range of 150% to 185%.

Data sources and availability

The main part of the analysis in this article is derived from **structural business statistics (SBS)**, including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include the **PRODCOM** statistics on the production of manufactured goods.

Context

Enterprises in the fuel processing and chemicals sector operate within a highly regulated framework that extends from the supply of the raw materials, through their processing to the treatment of waste. The Registration, Evaluation and Authorisation of Chemical substances (the so-called **REACH** Regulation) came into force on 1 July 2007, with the main aims of improving the protection of human health and the environment from risks posed by chemicals. The first list of 15 chemicals to undergo scrutiny was published by the **European Chemicals Agency** in October 2008. A new **European Parliament** and **Council Regulation** on the classification, labelling and packaging of chemical substances and mixtures (CLP) was adopted in December 2008, in order to align the labelling and description of hazards around the world. The CLP Regulation entered into force on 20 January 2009, with the deadline for substance classification according to the new rules by 1 December 2010 and for mixtures by 1 June 2015.

The fuel processing and chemicals sector faces a number of key challenges; these are energy and raw materials supply, climate change and barriers to market entry in emerging countries. Against this background, the [High Level Group on the Competitiveness of the European Chemicals Industry](#), which was first proposed by the [European Commission](#) in June 2007 ([COM\(2007\) 418](#)), released its final strategy report in February 2009. The strategies focus on more innovation and research (see the importance of this in the article called [Pharmaceuticals production statistics - NACE Rev. 1.1](#)), the responsible use of resources and a level playing field for sourcing energy and raw materials, and a drive to open world markets.

Petroleum and natural gas are used by petrochemical enterprises to produce a range of products; these concern basic petrochemicals such as aromatics (for example, naphthalene and xylenes), methanol, and olefins (for example, butadiene and acetylene), intermediate products (for example, ethyl benzene and phenol) and petrochemical products (for example, plastics, solvents, additives and agro-chemicals). Petrochemicals are then used by many other downstream sectors of the economy as a raw material for use in a myriad of products (for example, healthcare products, plastics packaging and synthetic rubber tyres).

The sector is touched by legislation at various levels, with environmental protection and health and safety prominent. The REACH and CLP legislations mentioned in the article on Fuel processing and chemicals production statistics concern forms of classifying, packaging and labelling chemicals. Other new legislation has looked at implications of the global chemicals trade. For example, the [European Parliament](#) and the [Council](#) adopted [Legislation](#) on the export and import of dangerous chemicals in June 2008, thereby implementing the [Rotterdam Convention on the Prior Informed Consent Procedure \(PIC\)](#) with a number of further provisions. The focus of this legislation is to protect human health and the environment from potential harm. As such, it complemented the 2007 Community Implementation Plan for the Stockholm Convention on Persistent Organic Pollutants (POPs)⁹⁸, which dealt with assessing measures to tackle the accumulation of adverse chemical substances in various ecosystems, across international boundaries. Civil protection legislation was also developed further in 2007, in part looking at the impact of potential chemical accidents and responses to that; Council Decisions on the civil protection mechanism ([Decision \(2007\) 779](#)) set the framework for a co-ordinated response by Member States and the Community in the event of [major emergencies](#) .

Pharmaceuticals production statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). The present article covers the manufacture of pharmaceuticals, which is part of the [fuel and chemicals production](#) sector. The activities covered in this article correspond to two [NACE Rev 1.1](#) classes, which are:

- the manufacture of basic pharmaceutical products (NACE Class 24.41);
- pharmaceutical preparations (NACE Class 24.42), which includes medicaments, vaccines, homeopathic preparations, dental fillings, bandages and dressings.

	R&D expenditure (EUR million)	Share of manufacturing R&D expenditure (%)
DK	1 050.7	44.3
DE	3 343.7	7.3
ES	605.8	18.0
FR	960.9	6.5
SE	1 475.9	22.8
UK	648.3	8.6

Table 5: Manufacture of pharmaceuticals, medicinal chemicals and botanical products (NACE Group 24.4). Expenditure, productivity and profitability, EU-27, 2006

Against the background of innovation concerns, it is interesting to note the [research and development \(R & D\)](#) expenditure within the pharmaceuticals manufacturing sector. Among the 20 Member States for which data are available⁹⁹ for either 2005 or 2006, intra-mural expenditure was EUR 8.7 billion, 90% of which was spent in Germany, Sweden, Denmark, France, the United Kingdom and Spain. In Denmark, as well as Slovenia, R&D expenditure in pharmaceutical manufacturing accounted for a little over two fifths of all R&D expenditure in manufacturing. This proportion was highest in Hungary, where it was nearly three fifths in 2006. In contrast, this share was well below 10% in Germany, France and the United Kingdom, among a number of Member States.

⁹⁹Belgium, Ireland, Italy, Luxembourg, Malta, the Netherlands and Finland, not available.

Structural profile

There were around 4.5 thousand [enterprises](#) throughout the [EU-27](#) for which pharmaceuticals manufacturing was their principal activity in 2006. These enterprises employed an estimated 610.0 thousand persons in the Member States, about three in every ten of the workers within all fuel processing and chemicals manufacturing activities. The [value added](#) generated by pharmaceutical activities in the EU-27 was EUR 70.5 billion in 2006, a little more than one third (36.0%) of the [turnover](#) generated. The sector also contributed three tenths of the value added generated across all fuel processing and chemicals manufacturing in 2005.

The vast majority (89.3%) of the value added generated by the pharmaceuticals sector of the EU-27 came from the pharmaceutical preparations manufacturing subsector (NACE Class 24.42), the remainder coming from the manufacture of basic pharmaceutical products (NACE Class 24.41).

The pharmaceuticals manufacturing sectors in Germany and France were larger than in other Member States and similar in size in terms of their value added generated in 2006; each contributed about one fifth of EU-27 value added. Although both of these countries showed moderate specialisation in these activities, specialisation was much stronger in Hungary, Ireland, Sweden, Belgium and particularly in Slovenia, where the pharmaceuticals sector contributed around 4.1% of non-financial business economy value added in 2006, over three times the equivalent share for the EU-27.

In the ten year period through until 2007, there was a consistent and steep rise in the production index for EU-27 pharmaceuticals manufacturing. Indeed, among the nine NACE groups within fuel processing and chemicals manufacturing for which data are available¹⁰⁰, the growth in the [output](#) of pharmaceuticals manufacturing (an average 6.1% per year) was the highest and about twice the rate of growth of the next highest that was recorded for basic chemicals manufacturing. Among the Member States, output growth was particularly strong in Greece (an average 14.1% per year) and Ireland (an average 18.0%), whereas there were moderate declines in Portugal and Finland.

EU-27 [tangible investment](#) in the pharmaceuticals manufacturing sector was EUR 8.4 billion in 2006, which was about one quarter of tangible investment across all fuel processing and chemicals manufacturing activities. Nevertheless, this represented a slightly lower share than the equivalent share in terms of value added, resulting in an investment rate for the pharmaceuticals sector (12.0%) that was beneath the average rate (14.4% in 2005) for fuel processing and chemicals manufacturing.

[Personnel costs](#) accounted for about one fifth (20.4%) of the pharmaceutical sector's operating expenditure in 2006, approaching twice the average share (11.7% in 2005) of all fuel processing and chemical manufacturing activities. This notably higher share was not, however, the result of particularly higher average personnel costs. Indeed, average personnel costs of EUR 56.1 per pharmaceutical employee in 2006 were almost identical to those across the whole of fuel processing and chemicals manufacturing in the EU-27 in 2005. The apparent [labour productivity](#) of those working in the EU-27's pharmaceutical sector in 2006 was about EUR 10.0 thousand higher than the average across fuel processing and chemicals manufacturing in 2005; each person employed in pharmaceuticals manufacturing in the EU-27 generated an average of EUR 115.6 thousand of value added in 2006. The value added generated per person employed in the pharmaceuticals manufacturing sector covered average personnel costs about twice over. In these terms, the EU-27 wage adjusted labour productivity ratio for the pharmaceuticals sector of 205.9% in 2006 was slightly higher than that (194.9% in 2005) for the whole of fuel processing and chemicals manufacturing. Among the Member States, wage adjusted labour productivity ratios for the pharmaceuticals sector were much higher than average (for fuel processing and chemicals manufacturing) in Belgium, Romania, Finland and Sweden, but much lower in Greece, Spain, Estonia (2005) and Poland (2005).

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include the [PRODCOM](#) statistics on the production of manufactured goods.

¹⁰⁰NACE Group 23.3 for the processing of nuclear fuels, not available.

Context

Enterprises in the fuel processing and chemicals sector operate within a highly regulated framework that extends from the supply of the raw materials, through their processing to the treatment of waste. The Registration, Evaluation and Authorisation of Chemical substances (the so-called [REACH Regulation](#)) came into force on 1 July 2007, with the main aims of improving the protection of human health and the environment from risks posed by chemicals. The first list of 15 chemicals to undergo scrutiny was published by the [European Chemicals Agency](#) in October 2008. A new [Regulation](#) on the classification, labelling and packaging of chemical substances and mixtures (CLP) was adopted in December 2008, in order to align the labelling and description of hazards around the world. The CLP Regulation entered into force on 20 January 2009, with the deadline for substance classification according to the new rules by 1 December 2010 and for mixtures by 1 June 2015.

The fuel processing and chemicals sector faces a number of key challenges; these are energy and raw materials supply, climate change and barriers to market entry in emerging countries. Against this background, the High Level Group on the Competitiveness of the European Chemicals Industry, which was first proposed by the [European Commission](#) in June 2007 ([Decision 2007/418](#)), released its final strategy report in February 2009. The strategies focus on more innovation and research, the responsible use of resources and a level playing field for sourcing energy and raw materials, and a drive to open world markets.

Legislation for medicinal products for human use and veterinary use continues to be updated to reflect new developments. These include the [November 2007 Regulation](#) updating rules governing the production, distribution and use of advanced therapy medicinal products, for processes such as gene therapy, somatic cell therapy and tissue engineering, by bringing them into a single, integrated framework. The European Commission also produced a Communication clarifying for the pharmaceutical sector the information to be provided in applications of medicinal products under paediatric investigation plans ([OJ 2008/C 243/01](#)).

However, the [European Commission](#) issued a Communication in December 2008 recognising that more needs to be done to address inequalities of availability of information about medicines, the growth in counterfeit medicines and the slow down in innovation. It laid out three legislative proposals:

- to tackle the growing issues of counterfeiting and illegal distribution of medicines ([COM\(2008\) 664 final](#));
- to enable citizens to have access to high-quality information on prescription-only medicines ([COM\(2008\) 662 final](#));
- to improve patient protection by strengthening the EU system for the safety monitoring ('pharmacovigilance') of medicines ([COM\(2008\) 664 final](#)).

Community action within the pharmaceuticals sector has had the dual objective of safeguarding public health by providing safe and effective medicines, while creating a business environment that stimulates research, boosts innovation and supports competitiveness.

Notes

Pipeline transport statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers pipeline transport statistics, corresponding to NACE Group 60.3, which is part of the [transport and storage](#) sector. The activities covered in this article are:

- the transport of gases, liquids, slurry and other commodities via pipelines;
- the operation of pump stations.

This article does not include the distribution (as opposed to the transport) of natural or manufactured gas via mains, or of water or steam.

Main statistical findings

The [EU-27](#)'s transport via pipelines sector (NACE Group 60.3) had approximately 130 [enterprises](#) which together generated EUR 11.0 billion of [turnover](#) in 2005 and as such its share in transport services (NACE Divisions 60 to 63) turnover was 1.0%. Although data is only available for a few Member States it is clear that in turnover terms this sector is relatively important in Italy which accounted for 18.3% of the EU-27's turnover in 2005, while Germany also recorded a large share (14.8%). [Employment](#) in this sector in the EU-27 was in excess of 16.8 thousand persons in 2005, with large workforces in Romania (7.9 thousand), Poland (3.4 thousand) and Italy (3.0 thousand).

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Context

The transport and storage sector focuses on transport services provided to clients for hire and reward. When analysing transport traffic volumes (for example, tonnes of freight) as presented in this article, it is important to bear in mind that these include own account transport as well as transport services for hire and reward. This is particularly important in road transport where, for example, a manufacturer might collect materials or deliver own [output](#), rather than contracting a transport service enterprise to do this. Equally, the use of own vehicles (typically passenger cars) accounts for a very large part of passenger transport. Such own account transport does not contribute towards the statistics on the transport services sector.

EU transport policy is based upon the 2001 White paper '[European transport policy for 2010: time to decide](#)' and the 2006 mid-term review in the European Commission's communication ([COM\(2006\) 314](#)) 'Keep Europe moving – sustainable mobility for our continent'. In 2007 the European Commission adopted a communication ([COM\(2007\) 606](#)) on 'Keeping freight moving', to make rail freight more competitive, facilitate modernisation of ports, and review progress in the development of sea shipping.

Environmental issues remain of great importance to this sector, as transport is a major source of emissions and noise. In 2008 the European Commission put forward a package of measures related to road and rail transport referred to as 'Greening Transport'. This included a communication ([COM\(2008\) 433](#)) summarising the packages and initiatives planned for 2009, a strategy to internalise the cost of transport externalities, a proposal for a Directive on road tolls for lorries, and a communication on rail noise. The overall thrust of the package is

to try to move towards more sustainable transport.

Plastics production statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). The present article covers the production of plastics, corresponding to [NACE Rev 1.1 Group 25.2](#), which is part of the [rubber and plastics](#) sector. This article covers the manufacture of plastic products, including:

- plastic sheets, pipes and tubes;
- plastic packaging goods (such as bags, containers and bottles);
- plastic products for the construction sector (such as doors, frames and baths);
- other plastic products (such as insulating and lighting fittings).

Note that the article does not cover the manufacture of plastic games, toys, footwear, furniture or linoleum.

	Enterprises (thousand)	Turnover (EUR million)	Value added (EUR million)	Persons employed (thousand)	Share in total (%)

Plastic boxes; cases; crates & similar articles for the conveyance or packing of goods	25.22.13.00	6 028	4	2 484 kg	0.7

(1) Excluding products of a generic nature (other), sales of services such as repair, maintenance and installation; estimates; threshold of production value set at EUR 6 billion; the rounding base indicates the magnitude of the rounding employed to protect confidential cells (in the case of PRODCOM code 25.24.90.60, the value lies within the range +/- EUR 0.5 million of the reported value).

Source: Eurostat (PRODCOM)

Table 4: Plastics (CPA Group 25.2). Production of selected products, EU-27, 2007 (1)

According to [Plastics Europe](#), the EU-27 together with Norway and Switzerland produced 65.6 million tonnes of plastics in 2007, accounting for a quarter of global production. There are a wide range of applications for plastics across many manufacturing activities. Demand by converters of plastics in the EU-27, Norway and Switzerland was for a total 52.5 million tonnes, of which just over one third (37%) was for packaging, a further fifth (21%) for building and construction and a little under one tenth (8%) for the automotive applications.

Structural profile

The plastics manufacturing sector (NACE Group 25.2) employed about 1.4 million persons across the EU-27 in 2006, about eight in every ten workers within rubber and plastics manufacturing. These persons were employed by some 57.2 thousand [enterprises](#), which generated an estimated [value added](#) of EUR 60.0 billion from turnover of EUR 209.7 billion in 2006.

The value added generated by the manufacture of other plastics (NACE Class 25.24), covering the production of goods such as plastic tableware and kitchenware as well as electrical insulating, was the largest activity within this sector, generating two fifths of EU-27 value added in 2006. A further quarter (25.4%) came from the manufacture of plastic plates, sheets, tubes and profiles manufacturing (NACE Class 25.21), while the manufacture of plastic packing goods (NACE Class 25.22) and builders' ware (NACE Class 25.23) provided the remainder.

The plastics manufacturing sector in Germany generated more value added in 2006 than that of any other Member State, accounting for over one quarter (28.1%) of the EU-27 total, almost twice the contribution of the next highest share from the United Kingdom (15.1%). There was not a particularly strong level of relative specialisation in value added terms within the plastics manufacturing sector. The relative contribution of the value generated by this sector to total value added in the [non-financial business economy](#) was highest in Slovenia, where it was about two thirds more than the EU-27 average.

For most of the plastics manufacturing subsectors, EU-27 [production indices](#) in the period between 1997 and 2007 followed a broad pattern of growth through until 2000 followed by a year or two of stagnation or contraction before a further upswing in output through until the end of the period. In this respect, the development of the output of builders' ware of plastic manufacturing was something of an anomaly. Over the same ten year period, the production index declined by a total of 6.6%, with upturns in 1998, 2003 and 2006 being followed immediately by declines.

Expenditure and productivity

[Tangible investment](#) in the plastics manufacturing sector in 2006 was valued at EUR 39.9 billion, representing about three quarters (76.2%) of all tangible investment across the EU-27's rubber and plastics manufacturing activities, resulting in an investment rate of 15.0%.

The average value added generated by each person employed within the EU-27's plastics manufacturing sector was EUR 43.4 thousand in 2006, which was EUR 13.4 thousand higher than the average [personnel costs](#) of each

employee (note the latter does not include self proprietors). As a result, the wage adjusted labour productivity ratio of the plastics manufacturing workforce was 144.7% in 2006, almost identical to the average for the whole of rubber and plastics manufacturing. This was also the case among a majority of the Member States for which data are available¹⁰¹, with exceptions limited to Bulgaria (where this ratio was 20 percentage points higher for plastics manufacturing), and to Slovakia and the Czech Republic (where it was between 20 and 30 percentage points lower for plastics manufacturing).

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include the [PRODCOM](#) statistics on the production of manufactured goods.

Context

Recent legislation within this area has focused on environmental issues, with a key development being the adoption of the revised [Waste Framework Directive](#) of the [European Parliament](#) and of the [Council](#) in November 2008. This sets out the basic concepts and definitions related to waste management and lays down waste management principles such as the 'polluter pays principle' or the 'waste hierarchy'. With regard to the rubber and plastics manufacturing sector, the Directive obliges Member States to take measures to promote high quality recycling and, to this end, set up separate collections of waste. By 2020, the recycling of waste materials such as plastics, among others, from households should be increased to a minimum of 50% by weight. End-of-waste criteria that provide a high level of environmental protection and an environmental and economic benefit should be laid down for tyres.

The production of plastic begins with the distillation of heavy crude oil into hydrocarbon fractions, the most important of which is called naphtha. Polymerisation and polycondensation are the two key processes used to produce plastics. Plastics can be grouped into two main polymer families: these are thermosets, which do not soften once moulded; and thermoplastics, which soften on heating and then harden on cooling.

Notes

Post and courier sector statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#) . According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers post and courier sector statistics, corresponding to NACE Group 64.1, which is part of the [media and communications](#) sector. The activities covered in this article are:

- national post activities (NACE Class 64.11), which include the pick-up, transport and delivery (domestic or international) of mail and parcels, and other services such as P.O. boxes.
- other courier activities (NACE Class 64.12), which include mainly express courier services, where enterprises have widened their initial focus on business documents towards the transfer of packages and freight, blurring the distinction between courier and transport enterprises.

	2002	2003	2004	2005	2006
Total number of permanent post offices (units)	103 176	101 602	99 801	100 182	100 366
of which, staffed by people from outside the administration (%)	36,5	35,9	35,6	36,8	40,7
Number of letter-post items, domestic service (million)	112 769	112 764	116 866	117 227	115 135
Number of letter-post items, international service-dispatch (million)	2 902	2 905	2 785	2 712	2 686
Ordinary parcels, domestic services (million)	1 073	1 041	1 066	1 013	990

(1) Letter-post services: the indicator covers items of correspondence (ordinary letters and postcards, direct mail, registered mail, insured mail) and other letter-post items (books, catalogues, newspapers and periodicals).

(2) Reserved area: refers to the standard letter-post service, where USPs enjoy exclusive rights to provide services. The reserved area is delineated at country level within weight/price limits given by the EC postal directives (97/67/EC and 2002/39/EC). Country definitions for the reserved area vary, so direct comparisons between countries should be made with prudence. In this publication it is expressed in terms of the percentage of the total letter post services.

(3) On-time delivery: the indicator refers to the share of priority letters delivered on-time according to national performance indicators, the standard measured is D+1.

(4) Price and on-time delivery, 2004.

(5) On-time delivery is calculated at D+3.

(6) On-time delivery is calculated at D+2.

Table 4: Post and courier activities (NACE Group 64.1). Expenditure, productivity and profitability, EU-27, 2006

Focus on postal infrastructure and transport of postal items

According to data collected by the UPU from its postal administration members, there were about 100.4 thousand permanent post offices in the EU-27 in 2006. This was slightly more than in 2004 or 2005, and equivalent to one permanent post office for every 4.9 thousand inhabitants on average.

The number of letter-items for both domestic and international dispatch was 117.8 billion in the EU-27 in 2006, about 2 billion less than in 2004 or 2005 and equivalent to an average of 238 letters per inhabitant. Ordinary parcels for both domestic and international dispatch amounted to 1.0 billion items in 2006, again slightly lower than the previous two years. For both letters and parcels, domestic deliveries accounted for the vast majority of the total, 98.5% for letters and 97.7% for parcels.

According to Eurostat's Inquiry on Postal Services, among the Member States for which data is available, mail deliveries in the 'reserved area' (where universal service providers have exclusive rights) ranged from 39% of letter-post services in Estonia up to 94% in Malta, with Finland, Sweden and the United Kingdom reporting no reserved area. The price for a standard letter was 20 cents or less in Romania, Malta and Slovenia, while it reached 60 cents or more in Finland, Denmark and Italy.

Structural profile

There were approximately 40.0 thousand enterprises in the EU-27's post and courier activities (NACE Group 64.1) sector in 2005. With close to 1.9 million persons employed, this sector represented 38.4% of the media and communications (NACE Divisions 22 and 64) workforce in 2005. This sector's contribution in terms of output was much lower, 13.1% in terms of turnover and 17.2% in terms of value added. National post activities (NACE Class 64.11) was the largest of the two subsectors within the post and courier activities sector, accounting for slightly less than two thirds both of sectoral value added and employment in 2005, the remainder being accounted for by courier activities (NACE Class 64.12).

The five largest EU economies were also the five largest contributors to the post and courier activities sector in 2006, whether measured in value added or employment terms. Looking at the relative contribution of post and courier activities to national non-financial business economy value added, relatively few Member States were particularly specialised or unspecialised in these activities. The most specialised was France where post and courier activities generated 1.4% of non-financial business economy value added, only slightly above the EU-27 average of 1.1%; the least specialised countries included the Baltic Member States, Spain and Cyprus where post and courier activities contributed around 0.5% of non-financial business economy value added. It should be noted that no recent data is available for Luxembourg which, traditionally, is specialised in these activities.

Annual [short-term statistics](#) for post and courier activities in the EU-27 provide a picture of the development of the turnover index over the period 2000 to 2007 – see [Media and communications statistics - NACE Rev. 1.1](#) . During this period there was uninterrupted year on year turnover growth in this sector, on average 4.1% per year, compared with an average growth rate of 5.3% per year for non-financial services (NACE Sections G to I and Divisions 72 and 74).

Expenditure and productivity

In the EU-27's post and courier activities [tangible investment](#) was valued at EUR 3.0 billion in 2006, equivalent to 5.0% of value added: this [investment rate](#) was the fifth lowest of all non-financial business economy NACE groups in 2005 or 2006. More than half of operating expenditure in 2005 was accounted for by [personnel costs](#) ; this was the fourth largest share of personnel costs recorded among all NACE groups in the non-financial business economy, mainly influenced by the high share recorded in national post activities where personnel costs took up more than two thirds (68.6%) of [operating expenditure](#) . In other courier activities, personnel costs still represented more than one third (35.5%) of operating expenditure in 2005, just over double the non-financial business economy average in the same year.

With EUR 32.2 thousand of value added generated per person employed in 2005, the EU-27's post and courier services sector recorded a relatively low level of apparent [labour productivity](#) compared with most other activities, as the non-financial business economy average was EUR 10.1 thousand above this value. Average personnel costs were EUR 27.6 thousand per employee in the EU-27, only slightly below the non-financial business economy (EUR 1.3 thousand below) in 2005. As a consequence, the [wage-adjusted labour productivity ratio](#) for post and courier services was extremely low, 116.6% in the EU-27 in 2005, significantly below the non-financial business economy average of 146.5% and the media and communications average of 188.7% in the same year. The wage-adjusted labour productivity ratio was higher for other courier activities (131.0%), while it was as low as 110.0% for national post activities in the EU-27 as a whole. Most Member States¹⁰² recorded a low wage-adjusted labour productivity ratio for post and courier activities, although Sweden was the only one that recorded a ratio below parity (100%) indicating that average personnel costs exceeded apparent labour productivity.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include the postal statistics database [UPU](#) and Eurostat, Inquiry on Postal Services 2007.

Context

This sector gathers together several activities linked to media and communication activities, however, within this group a distinction has to be made between traditional activities (for example, postal services) for which the level of activity is rather stable and other newer activities (such as mobile telephony and electronic publishing), for which growth developments are more marked.

In most Member States, universal service providers (USPs)¹⁰³ still operate as a monopoly and have exclusive rights, balanced by the fact that they have a universal service obligation. Private operators dominate the express services market, providing letter and parcel services, specifically to the business-to-business, direct mail and business-to-private segments of the market. Since the middle of the 1990's there have been gradual developments towards market liberalisation for post and courier services, with parcels and express services markets now fully open to competing operators. The latest amendment ([2008/6](#)) of the European Parliament and of the Council to the 1997 Directive on Community postal services was adopted in February 2008 and set out a timetable to abolish remaining restrictions on mail deliveries under 50 grams (known as the 'reserved area'

¹⁰²Cyprus and the Netherlands, 2005; the Czech Republic, Ireland, Luxembourg, Malta, Poland and Slovenia, not available.

¹⁰³The term USP takes account of the possibility that operators are no longer public organisations.

for national operators) and open up Europe's postal sector to full competition. The deadline for full market opening is 31 December 2010 for just over half of the Member States and 31 December 2012 for the remainder.

Table 3b: Key indicators, postal and courier activities (NACE Division 53), 2009 - Source: Eurostat (sbs_na_1a_se_r2)

Main statistical findings

Structural profile

The postal and courier services (Division53) sector is one characterised by widespread changes that may be linked to the deregulation of markets that were previously dominated by national postal monopolies. Across the EU-27 there were an estimated 50 thousand postal and courier services enterprises in 2009. Together they employed 1.8 million persons, equivalent to 1.3% of all persons employed in the non-financial business economy (SectionsB to J and L to N and Division95) and 17.0% of those persons working in the whole of transportation and storage services (SectionH). They generated EUR59691 million of value added which was 1.1% of the non-financial business economy total and 13.7% of the transportation and storage added value.

The apparent labour productivity of the EU-27's postal and courier services sector in 2009 was EUR33 thousand per person employed, which was below both the non-financial business economy average of EUR41.6 thousand per person employed and the transportation and storage average of EUR41 thousand per person employed. Average personnel costs per employee within the EU-27's postal and courier services sector were slightly below average: EUR28.5 thousand for postal and courier services compared with EUR30.0 thousand for the non-financial business economy and EUR31.2 thousand for transportation and storage services.

The wage-adjusted labour productivity ratio combines these two previous indicators and shows the extent to which value added per person employed covers average personnel costs per employee. Due to the relatively low levels of labour productivity and only slightly inferior average personnel costs, the EU-27's postal and courier services sector had a lower than average wage-adjusted labour productivity ratio, standing at 116.4% in 2009, compared with a non-financial business economy average of 138.8% and a transportation and storage average of 132.1%.

The gross operating rate (the relation between the gross operating surplus and turnover) stood at 10.3% for the EU-27's postal and courier services sector in 2009, which was some 0.6 percentage points above the non-financial business economy average (9.7%), but lower than the transportation and storage average (12.2%).

Sectoral analysis

Around nine out of every ten enterprises within the EU-27's postal and courier services sector were classified within other postal and courier activities (Group53.2), reflecting the deregulated market structure for this particular activity where internationally known enterprises compete against local competitors for the courier business. However, the postal activities under universal service obligation (Group53.1) subsector remains a concentrated activity. It was also the larger activity (other than for an enterprise count), with more than three fifths (62.6%) of the sectoral workforce and nearly two thirds (65.7%) of the added value generated in the EU-27's postal and courier services sector in 2009.

EU-27 postal activities under universal service obligation recorded somewhat higher apparent labour productivity (EUR35 thousand per person employed) in 2009 than that recorded for other postal and courier activities (EUR30 thousand per person employed); both subsectors had apparent labour productivity ratios that were below the non-financial business economy average or the transportation and storage average. Average personnel costs peaked at EUR30.8 thousand for EU-27 postal activities under universal service obligation, while the corresponding value for other postal and courier activities was EUR6.4 thousand per employee lower. The wage-adjusted labour productivity ratio shows that apparent labour productivity exceeded average personnel costs within the other postal and courier activities subsector (wage-adjusted labour productivity ratio of 124.5%), while for postal activities under universal service obligation the corresponding rate was 113.1%; both of these ratios were below the non-financial business economy average (138.8%) and the transportation and storage average (132.1%).

For the gross operating rate, the latest rates available for 2009 also reflected quite a similar level of performance in the two subsectors that compose the postal and courier services sector, as the other postal and courier activities subsector recorded an operating rate of 11.6% across the EU-27, while the corresponding rate for postal activities under universal service obligation was 9.2%; the two rates were situated either side of the non-financial business economy average (9.7%).

Country analysis

Germany accounted for 23.3% of the EU-27's value added within the postal and courier services sector in 2009 and for a slightly higher share (24.7%) of the EU-27's workforce. In value added terms, the next highest contributors were the United Kingdom (15.6% of the EU-27 total) and Italy (13.6%); none of the remaining Member States had a double-digit share.

The pattern of below average apparent labour productivity and somewhat higher average personnel costs observed for the EU-27's postal and courier services sector was repeated in most Member States in 2009. The highest level of apparent labour productivity was recorded in Ireland (EUR51.6 thousand per person employed), while Italy, Austria, Belgium and Denmark (2008) were the only other Member States to record apparent labour productivity over EUR40 thousand per person employed. Ireland also registered the highest level of average personnel costs (EUR51.1 thousand per employee). Combining these two indicators, the resulting wage-adjusted labour productivity ratio ranged from a relatively modest 144.0% in the Netherlands and 137.1% in Slovakia, down to less than 100% in the Czech Republic and Lithuania.

The gross operating rate of the postal and courier services sector was also highest in the Netherlands (16.8% in 2009), closely followed by Italy (16.6%). Almost half of the Member States for which data are available reported a gross operating rate for the postal and courier services sector that was in single figures. The lowest rate was registered in Lithuania (-8.1%), as a result of total personnel costs being higher than the value added that was generated within the postal and courier services sector.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the postal and courier services sector in the EU-27, as covered by NACE Rev.2 Division53. This division includes postal and courier activities, such as pickup, transport and delivery of letters and parcels under various arrangements. Local delivery and messenger services are also included.

Postal activities under universal service obligation includes the services provided by universal service providers using the universal service infrastructure, including retail locations, sorting and processing facilities, and carrier routes to pickup and deliver the mail. The delivery can include letter-post, in other words letters, postcards, printed papers (newspapers, periodicals, advertising items, and so on), small packets, goods or documents. Also included are other services necessary to support the universal service obligation and the collection of letter-mail and parcels from public letter-boxes or from post offices.

Other postal and courier activities include all other such services falling outside of the scope of the universal service obligation; this also includes home delivery services.

This NACE division is composed of two groups:

- postal activities under universal service obligation (Group53.1);
- other postal and courier activities (Group53.2).

The information presented in this article excludes financial services activities (such as postal giro, postal savings activities and money order activities) as these form part of Division64 covering financial service activities, except insurance and pension funding; note these activities are excluded from the coverage of the non-financial business economy.

Precious and non-ferrous metal production statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). The present article covers the production of precious and non-ferrous metals, corresponding to [NACE Rev 1.1 Group 27.4](#), which is part of the [metals and metal products](#) sector. The activities covered in this article consist of a wide range of metals other than iron and steel, including:

- precious metals (such as gold, silver and platinum);
- common metals (such as aluminium, lead, zinc, tin, copper, chrome, nickel and manganese).

	Highest value added (1)		Largest number of persons employed (1)		Most specialised: share in non-financial business economy (%) (2)

Table 2: Manufacture of basic precious and non-ferrous metals (NACE Group 27.4). Expenditure, productivity and profitability, EU-27, 2006

There were 3.6 thousand [enterprises](#) in the [EU-27](#)'s basic precious and non-ferrous metals manufacturing (NACE Group 27.4) sector, which generated EUR 17.8 billion of [value added](#) and employed 221.5 thousand persons in 2006, making it one of the smaller activities within the metals and metal products (NACE Subsection DJ) manufacturing sector; it accounted for 7.3% of value added and 4.4% of [employment](#) within metals and metal products manufacturing.

By far the largest of the five NACE class activities within the EU-27's basic precious and non-ferrous metals manufacturing sector was the aluminium production subsector (NACE Class 27.42), which generated EUR 9.1 billion of added value in 2006. The copper production subsector (NACE Class 27.44) was the next largest, creating added value across the EU-27 of EUR 3.9 billion, the equivalent of just over a fifth (21.8%) of the total within the activities of basic precious and non-ferrous metals.

As with metals and metal products manufacturing as a whole, Germany had the largest basic precious and

non-ferrous metals manufacturing sector in the EU-27; it contributed over one quarter (28.1%) of the value added generated by basic precious and non-ferrous metals manufacturing in the Member States in 2006. In relation to its [non-financial business economy](#), the basic precious and non-ferrous metals manufacturing sector of Bulgaria (1.3%) generated by far the highest value added in 2006, approaching five times the average contribution within the EU-27.

There was a distinct parting of the developments in the production indices for basic precious and non-ferrous metals manufacturing and metals and metal products manufacturing as a whole after 2000. Whereas the output of metals and metal products manufacturing stabilised in the period between 2000 and 2003 before rising strongly through until 2007, the [output](#) of basic precious and non-ferrous metals manufacturing declined steadily through until 2003 after which there was a muted and uncertain rebound to a level in 2007 that remained 3.5% below its relative peak of 2000.

Expenditure and productivity

[Tangible investment](#) in the EU-27's basic precious and non-ferrous metals manufacturing sector was EUR 2.3 billion in 2005, corresponding to 8.5% of total tangible investment in the metals and metal products manufacturing sector. When compared with the value added generated by this sector, this produced an [investment rate](#) of 15.8% in 2005, notably higher than the rate (12.2%) across the whole of the metals and metal products manufacturing sector in the same year.

The proportion of [operating expenditure](#) accounted for by personnel costs in the basic precious and non-ferrous metals sector was low (8.1% in 2006), less than half the average across metals and metal products manufacturing (19.2%) and among the lowest rates for industrial activities. This was despite average [personnel costs](#) being about EUR 10.5 thousand per employee higher in 2006 than the metals and metal products manufacturing average.

Each person employed in the EU-27's basic precious and non-ferrous metals sector contributed an average of EUR 80.6 thousand of value added in 2006, about EUR 32.5 thousand per person employed more than the average for metals and metal products manufacturing. This relatively high level of apparent [labour productivity](#) more than covered high average personnel costs, resulting in a [wage-adjusted labour productivity ratio](#) of 188.5% for the EU-27's basic precious and non-ferrous metals sector in 2006, much higher than the ratio (149.3%) for metals and metal products manufacturing as a whole. This was a characteristic noted in the vast majority of Member States, but particularly so in Bulgaria, Latvia, Lithuania, Spain and Slovakia. The principal exceptions were Ireland and Portugal (2005), where wage-adjusted labour productivity ratios of the basic precious and non-ferrous metals sector were below metals and metal products manufacturing averages.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Context

The metals and metal products manufacturing sector is part of a diverse and interwoven economic network that incorporates upstream sectors and large downstream segments of manufacturing such as the transport equipment manufacturing and construction sectors. The challenges faced by the EU's metals and metal products manufacturing sector therefore have direct and indirect consequences on many other parts of the economy. Looking ahead, a Communication ([COM\(2008\) 108](#)) from the [European Commission](#) to the [Council](#) and the [European Parliament](#) on the competitiveness of the metals industries was adopted in February 2008, and highlighted the challenges to be faced.

The EU-27 is largely dependent on imports of ore and concentrates for steel, ferro-alloys and non-ferrous metals production; it produces only 1.7% of the world's nickel, 2% of its iron ore and 5% of its copper ([SEC\(2007\)](#))

771). Access to minerals and secondary raw materials at competitive prices is important, especially given the exhaustion of certain deposits in the EU-27 over time or their absence, and supply constraints that have been exacerbated by the strong growth in international demand from emerging economies such as China and India. This concern was part of a raw materials initiative of the European Commission ([COM\(2008\) 699](#)).

Parts of the metals and metal products manufacturing sector are highly [energy-intensive](#) . Energy costs for the EU-27's metals and metal products manufacturing sector accounted for 4.4% of purchases of goods and services in 2006, which was the third joint highest proportion among the industrial structural business statistics sectors, albeit well behind non-energy mining and quarrying (10.1%) and other nonmetallic mineral products (9.5%). Within this sector, however, energy costs in the casting of metals subsector accounted for 7.2% of purchases of goods and services in 2006 and in the first processing of ferrous metals as much as 7.9%. This level of energy consumption has important implications for energy and environmental (particularly climate change) policy.

The metals and metal products manufacturing sector is covered by a [Directive on Integrated Pollution Prevention and Control \(IPPC\)](#) and [REACH](#) . A proposal from the European Commission on the review of EU [Emissions trading system \(ETS\)](#) adopted in January 2008 ([COM\(2008\) 30](#)) foresees the inclusion of non-ferrous metals from 2013 onwards, along with some transitional measures to avoid 'carbon leakage'.

Table 4b: Key indicators, printing and reproduction of recorded media (NACE Division 18), 2009 - Source: Eurostat (sbs_na_ind_r2)

Main statistical findings

Structural profile

The printing and reproduction of recorded media (Division 18) sector was made-up of 127 thousand enterprises in the EU-27 in 2009 and together they employed around 846 thousand persons. This sector's value added was EUR34000 million in 2009, equivalent to 0.6% of the non-financial business economy (Sections B to J and L to N and Division 95) total and 2.4% of the manufacturing (Section C) total.

The apparent labour productivity of the EU-27's printing and reproduction of recorded media sector in 2009 was EUR40 thousand per person employed, just below the non-financial business economy average of EUR41.6 thousand per person employed and further below the manufacturing average of EUR46 thousand per person employed. Average personnel costs within the EU-27's printing and reproduction of recorded media sector were EUR33.3 thousand per employee, about one tenth higher than the non-financial business economy average (EUR30.0 thousand per employee) but below the manufacturing average (EUR34.5 thousand per employee).

The ratio of the gross operating surplus to turnover is a measure of operating profitability, referred to here as the gross operating rate. In 2009, the EU-27's printing and reproduction of recorded media sector had a gross operating rate of 9.2%, which was just below the non-financial business economy average (9.7%) and higher than the manufacturing average (7.0%); this was the fifth highest level of profitability (using this measure) in 2009 among the NACE divisions within manufacturing (22 divisions with data available).

Sectoral analysis

The printing and reproduction of recorded media sector comprises two subsectors. Within the EU-27, the printing and related services subsector (Group 18.1) dominates, as the reproduction of recorded media subsector (Group 18.2) is smaller according to all of the main economic measures. There were 120.8 thousand enterprises in the EU-27's printing and related services subsector in 2009 employing 819.6 thousand persons, compared with 6.1 thousand enterprises in the reproduction of recorded media subsector which employed 26.0 thousand persons. The EU-27's printing and related services subsector generated EUR32228 million of value added in 2009, a 94.8% share of the sector's value added.

The ratios presented in Table 2b show that the printing and related services subsector had lower apparent labour productivity and average personnel costs than the smaller reproduction of recorded media subsector.

In fact, the EU-27's printing and related services subsector recorded apparent labour productivity of EUR39 thousand per person employed in 2009, which was well below the manufacturing average (EUR46 thousand), whereas the equivalent figure for the reproduction of recorded media subsector was EUR56 thousand per person employed. A similar situation could be observed for average personnel costs, with the difference that the value for the printing and related services subsector (EUR33.1 thousand per employee) was only slightly below the manufacturing average (EUR34.5 thousand).

The [wage-adjusted labour productivity ratio](#) results from a combination of the apparent labour productivity and average personnel costs indicators. Due to its low apparent labour productivity the EU-27's printing and related services subsector had a relatively low wage-adjusted labour productivity ratio in 2009, 118.9%, which was below the manufacturing average (132.1%) and the non-financial business economy average (138.8%). In contrast, the reproduction of recorded media subsector recorded a wage-adjusted labour productivity ratio of 147.4%, above both of these benchmarks. For the gross operating rate, both of the printing and reproduction of recorded media subsectors recorded rates above the manufacturing average (7.0%), with that for printing and related services (9.0%) below the non-financial business economy average (9.7%), whereas that for the reproduction of recorded media (12.0%) was higher.

Country analysis

Among the Member States, Germany had the highest share of value added within the EU-27's printing and reproduction of recorded media sector in 2009: the 22.4% German share of the EU-27 total was lower than its corresponding share of EU-27 value added within manufacturing (27.3%) as a whole. The next largest Member States in the printing and reproduction of recorded media sector were the United Kingdom (16.4% of the EU-27 total) and Italy (11.6%), both of which contributed more to the EU-27's total value added in this sector than they did to EU-27 manufacturing as a whole. France (11.2%) was the only other Member State to contribute more than one tenth of the EU-27's value added in the printing and reproduction of recorded media sector in 2009.

The relative importance of the printing and reproduction of recorded media sector was highest in Slovenia where it accounted for 0.9% of non-financial business economy value added and in Estonia, Belgium and Austria where its share was 0.8%; Croatia and Switzerland were also relatively specialised in this sector. The least specialised Member States for the printing and reproduction of recorded media sector were Lithuania, Poland, Latvia and France, where this sector contributed less than 0.5% of non-financial business economy value added in 2009; a situation that was also observed in Norway.

In 2009, Romania and Bulgaria recorded wage-adjusted labour productivity ratios for the printing and reproduction of recorded media sector in excess of 200%, indicating that apparent labour productivity per person employed was more than double average personnel costs per employee. These two Member States, as well as Austria and Estonia, were the only ones in 2009 (with data available) that recorded a higher wage-adjusted labour productivity ratio for the printing and reproduction of recorded media sector than they did for their respective non-financial business economies. At the other end of the scale, Greece recorded a wage-adjusted labour productivity ratio for the printing and reproduction of recorded media sector below 100%, as average personnel costs per employee were higher than apparent labour productivity per person employed.

In terms of operating profitability, Romania and Bulgaria recorded the highest gross operating rates among the Member States for the printing and reproduction of recorded media sector in 2009, while France and Sweden recorded the lowest. A majority of Member States recorded higher gross operating rates for the printing and reproduction of recorded media sector in 2009 than they did in the non-financial business economy as a whole, most notably Bulgaria, Romania, Austria and Portugal.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the printing and reproduction of recorded media sector in the EU, as covered by NACE Rev.2 Division18. This division includes the printing of products, such as newspapers, books, periodicals, business forms, greeting cards, and other materials, and associated support activities. The preparatory support activities (such as composing, typesetting, phototypesetting, pre-press data input, electronic make-up, preparation of data files for multi-media applications, plate-making, cylinder preparation and plate processing) and finishing activities (including bookbinding, mounting, folding, cutting, collating, stamping, stitching, perforating, embossing) are an integral part of printing. Processes used in printing include a variety of methods for transferring an image from a plate, screen or computer file to a medium, such as paper, plastics, metal, textile articles, or wood.

This division also includes the reproduction (from master copies) of recorded media, such as compact discs, video recordings, software on discs or tapes, records and so on.

This NACE division is composed of two groups:

- printing and related services (Group18.1);
- the reproduction of recorded media (Group18.2).

Though printing and publishing can be carried out in combination it is less and less the case that these distinct activities are carried out at the same physical location; this division excludes [publishing activities](#) (SectionJ). Also excluded are silk screen-printing on textiles and wearing apparel (part of the [manufacture of textiles](#) , Division13) and the original production of master copies, as well as the reproduction of motion picture films for theatrical distribution (part of [motion picture, video and television programme production, sound recording and music publishing activities](#) , Division59).

Printing and reproduction statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers printing and reproduction statistics, corresponding to NACE Groups 22.2 and 22.3, which are part of the [media and communications](#) sector. The activities covered in this article are:

- printing, whether on paper or other supports, corresponding to NACE Group 22.2;
- reproduction of recorded media (NACE Group 22.3), which includes:
 - reproduction services for sound and video recording (NACE Classes 22.31 and 22.32);
 - reproduction services for software (NACE Class 22.33).

Table 1: Printing and service activities related to printing; reproduction of recorded media (NACE Groups 22.2 and 22.3). Structural profile: ranking of top five Member States in terms of value added and persons employed, 2006

Main statistical findings

Structural profile

Source: Eurostat (STS)

Figure 1: Printing and service activities related to printing; reproduction of recorded media (NACE Groups 22.2 and 22.3). Index of production, EU-27 (2000=100)

The 138.9 thousand [enterprises](#) that make up the [EU-27](#)'s printing and reproduction of recorded media sector (NACE Groups 22.2 and 22.3) [employed](#) 997.7 thousand persons in 2006, around one fifth (20.5%) of the media and communications (NACE Divisions 22 and 64) workforce. These enterprises generated EUR 124.7 billion of [turnover](#) and EUR 47.3 billion of [value added](#); in [output](#) terms the contribution of this sector to the media and communications total was considerably less than in employment terms, this sector's value added for example amounting to 13.5% of the total.

Among the two NACE groups that make up the printing and reproduction of recorded media sector, printing and service activities related to printing (NACE Group 22.2, hereafter referred to as printing) was dominant by all measures studied, with 88.0% of the sector's value added and 96.4% of the workforce. The output

of these two activities developed differently in recent years, with the growth in the [production index](#) being remarkably strong for the reproduction of recorded media, while that for printing was below the industrial average.

Slightly less than one fifth of the EU-27's value added in the printing and reproduction of recorded media sector in 2006 was concentrated in each of the United Kingdom and Germany. Printing accounted for at least four fifths of value added in the printing and reproduction of recorded media sector in every Member State, except for Ireland, where the reproduction of recorded media generated 94.4% of sectoral value added. In fact, Ireland alone generated 71.8% of the EU-27's value added in the reproduction of recorded media subsector.

Expenditure and productivity

The EU-27's printing subsector recorded an [investment rate](#) of 15.7%, while for the reproduction of recorded media subsector the rate was just 8.5%. Equally, an analysis of [operating expenditure](#) shows differences between the subsectors: [personnel costs](#) accounted for 30.0% of operating expenditure for the printing subsector, and just 8.3% for the reproduction of recorded media subsector, the former being close to double the [non-financial business economy](#) average and the latter around half. Apparent [labour productivity](#) for the EU-27's printing subsector was EUR 43.3 thousand per person employed while the ratio reached EUR 156.6 thousand for the reproduction of recorded media in 2006. The difference in average personnel costs was less notable, ranging from EUR 32.1 thousand per employee for printing to EUR 38.4 thousand per employee for the reproduction of recorded media. These figures led to a [wage-adjusted labour productivity ratio](#) below the non-financial business economy average for the printing subsector (135.0%), while the reproduction of recorded media had a wage-adjusted labour productivity ratio of 408.2%, meaning that the value added per person employed in this subsector covered average personnel costs four times over. This was the second highest wage-adjusted labour productivity ratio recorded among any of the NACE groups within the non-financial business economy (with data available in 2005 or 2006).

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include [short-term statistics \(STS\)](#) .

Context

This sector gathers together several activities linked to media and communication activities, however, within this group a distinction has to be made between traditional activities (for example, [postal services](#)) for which the level of activity is rather stable and other newer activities (such as mobile telephony and electronic publishing), for which growth developments are more marked.

More so than many other industrial processes, printing has been revolutionised by [information technologies](#) . Information technology has created a number of electronic alternatives to traditional printing and at the same time enabled smaller and more flexible print-runs.

Professional, scientific and technical activity statistics - NACE Rev. 2

Data from June 2011, most recent data: Further Eurostat information, Main tables and Database

This article presents an overview of statistics for the [European Union's \(EU's\)](#) professional, scientific and technical services sector, as covered by [NACE Rev. 2](#) Section M. These activities often require a high degree of education and training and make specialised knowledge and skills available to users. In NACE the following seven divisions are included as part of this sector:

- legal and accounting activities (Division 69);
- activities of head offices and management consultancy activities (Division 70);
- architectural, engineering and technical consultancy services (Division 71);
- scientific research and development (Division 72);
- advertising (including direct mailing) and market research (Division 73);
- other professional, scientific and technical services such as design, photography, translation and interpretation services (Division 74);
- veterinary services for farm animals and pets (Division 75).

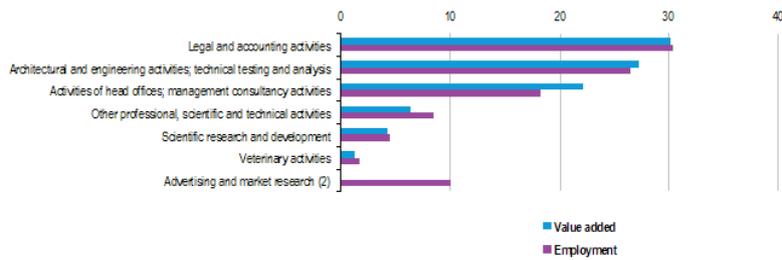

The professional, scientific and technical services sector does not include activities of holding companies that are not engaged in managing (which are classified as a financial activity), while management consultancy does not include educational consultancy activities (which are part of the education sector). Test drilling in connection with mining operations is considered part of the [mining and quarrying sector](#) (Section B) rather than technical consultancy.

Main statistical findings

Structural profile

There was a total of 3.4 million enterprises classified to the EU-27's professional, scientific and technical services sector (Section M) in 2009 and 11.0 million persons worked in this sector generating EUR 520700 million of value added. Enterprises providing professional, scientific and technical services are often small and this is reflected in the high proportion (16.5%) of the non-financial business economy (Sections B to J and L to N and Division 95) enterprise population that was classified to these activities; in contrast, this sector contributed 9.3% of non-financial business economy value added and 8.2% of its workforce.

The apparent labour productivity of the EU-27's professional, scientific and technical services sector in 2009 was

EUR 47 thousand per person employed, which was somewhat higher than the non-financial business economy average of EUR 41.6 thousand per person employed. **Average personnel costs** within the EU-27's professional, scientific and technical services sector were also higher than the non-financial business economy average, at EUR 40.5 thousand per employee; this was just over one third higher than the non-financial business economy average of EUR 30.0 thousand per employee. The relatively high level of average personnel costs per employee reflects the nature of the work done in the professional, scientific and technical services sector, where a relatively high proportion of staff have completed higher education and often professional studies thereafter (for example, to become an accountant or tax adviser). The consequence of average personnel costs that were proportionately more above the non-financial business economy average than the apparent labour productivity was a below average **wage-adjusted labour productivity ratio** : this was 117.0% for the EU-27's professional, scientific and technical services sector in 2009, well below the non-financial business economy average of 138.8% and the third lowest ratio within the non-financial business economy, ahead of the **construction sector** (Section F) and the **repair of computers and personal and household goods sector** (Division 95).

In contrast to the relatively low wage-adjusted labour productivity ratio, the **gross operating rate** for the EU-27's professional, scientific and technical services sector was relatively high – 17.8% in 2009 – which was 1.8 times as high as the non-financial business economy average of 9.7%. This reflected the fact that professional, scientific and technical services had relatively low operating costs apart from its elevated average personnel costs and as such the **gross operating surplus** was high relative to turnover.

Sectoral analysis

The professional, scientific and technical services sector can be divided into seven subsectors at the NACE division level. Legal and accounting activities (Division 69) combined with architectural, engineering, technical testing and analysis activities (Division 71) provided 57.4% of EU-27 sectoral value added and 56.8% of sectoral employment in 2009. Four of the six subsectors for which a complete set of data are available – only a partial set of information is available for advertising and market research activities for 2009 – contributed a slightly larger share of sectoral employment than sectoral value added, suggesting that these activities had a slightly lower than average level of apparent labour productivity. This pattern was counterbalanced mainly by the third largest subsector, namely the activity of head offices and of management consultancy activities (Division 70), which had a much higher share of sectoral value added (22.2%) than employment (18.2%). Advertising and market research accounted for one tenth of sectoral employment. The contribution of other professional, scientific and technical services (Division 74) was under 10%, that of scientific research and development was under 5%, and that of veterinary activities was under 2%.

Within the EU-27, the lowest levels of apparent labour productivity among the subsectors that make-up the professional, scientific and technical services sector were recorded for advertising and market research (EUR 39.0 thousand per person employed), for other professional, scientific and technical services (EUR 36 thousand per person employed) and for veterinary activities (EUR 35 thousand per person employed) – see Table 2b. All three of these subsectors reported apparent labour productivity which was below the non-financial business economy average (EUR 41.6 thousand per person employed). These three subsectors also reported the lowest average personnel costs per employee across the professional, scientific and technical services sector, although for this indicator only veterinary activities reported a level of average personnel costs (EUR 22.9 thousand per employee) that was below the non-financial business economy average (EUR 30.0 thousand per employee).

At the other end of the range, the subsector of activities of head offices and management consultancy recorded the highest levels of apparent labour productivity and average personnel costs in the EU-27 across the professional, scientific and technical services sector (at the NACE division level of detail) in 2009, with the productivity measure reaching EUR 58 thousand per person employed, while average personnel costs were EUR 54.5 thousand per employee. The EU-27's scientific research and development activities in 2009 recorded the unusual situation of a lower level of apparent labour productivity than average personnel costs, indicating that the wage-adjusted labour productivity ratio was below parity (at 95.6%). Due to its particularly high average personnel costs the activities of head offices and management consultancy recorded the next lowest wage-adjusted labour productivity ratio (106.0%), while the only subsector to report a wage-adjusted labour productivity ratio above the non-financial business economy average (138.8%) was veterinary activities, whose ratio reached 151.8%, pulled up by particularly low average personnel costs.

In a similar manner the EU-27's scientific research and development activities subsector recorded a particularly low gross operating rate of just 0.9% in 2009, indicating that the gross operating surplus was close to zero

as a result of personnel costs being almost equal to value added. Relatively low gross operating rates were also recorded for the advertising and market research subsector (10.0%) and the activities of head offices and management consultancy activities subsector (also 10.0%), although these were just above the non-financial business economy average (9.7%). In 2009, the four remaining subsectors within the EU-27's professional, scientific and technical services sector recorded gross operating rates that were above the sectoral average (17.8%), peaking at 32.5% for the legal and accounting services subsector.

Country analysis

The Netherlands, the United Kingdom and Luxembourg were the most specialised Member States in employment terms in the professional, scientific and technical services sector in 2009, as each employed more than 11% of their non-financial business economy workforce in these activities. The same three Member States, along with France (for which the employment data is based on employees and not persons employed), also occupied the top of the ranking in relation to the most specialised Member States for value added, peaking in Luxembourg, where 16.3% of non-financial business economy value added in 2009 was generated by the professional, scientific and technical services sector. The United Kingdom had the largest share of EU-27 value added (22.3%) and the largest share of EU-27 employment (18.5%) in this sector. This pattern was carried over into a more detailed analysis by NACE division, as the United Kingdom had the highest level of value added among the Member States for six out of the seven subsectors shown in Table 3, the one exception being scientific research and development where Germany had the highest share (32.1%) of EU-27 value added.

For each of the subsectors their share in non-financial business economy value added was higher in the United Kingdom than the average for the EU-27 as a whole, indicating that the United Kingdom's specialisation in professional, scientific and technical services was widespread across the full range of activities, rather than being dependent upon a particular subsector; a similar situation was observed in the Netherlands. The reverse situation was observed in Estonia, Hungary, Austria and Portugal, as each of the seven subsectors contributed less to non-financial business economy value added in these Member States than the average for the EU-27 as a whole. In several Member States there was a strong specialisation in just one or two of the subsectors, for example legal and accounting services in Luxembourg which contributed 10.1% of non-financial business economy value added, which was slightly more than 3.5 times as high as the average share for the EU-27 (2.8%). Other strong specialisations for legal and accounting services were also recorded in Cyprus, the United Kingdom and Ireland.

The apparent labour productivity of the professional, scientific and technical services sector in 2009 was less than EUR 20000 per person employed in Bulgaria, Romania, Hungary, Poland and the Baltic Member States, while it exceeded EUR 60000 per person employed in Belgium, Denmark (2008) and Ireland, while peaking at EUR 97400 per person employed in Luxembourg. However, after adjusting for the average personnel costs the ranking of countries according to the wage-adjusted labour productivity was rather different. While Hungary remained at the lower end – together with Italy, these were the only Member States where this ratio failed to pass 100% in 2009 – Bulgaria, Romania and Latvia moved to the top of the ranking, as their particularly low average personnel costs more than compensated for their low apparent labour productivity; they were joined by Portugal, Cyprus and the United Kingdom. In contrast, the particularly high average personnel costs in Belgium resulted in a low wage-adjusted labour productivity ratio, despite high apparent labour productivity.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

Many of the services covered within this article could be performed in-house by enterprises themselves, but purchasing (outsourcing) them from service providers enables them to focus on their core activities, taking advantage of the specialisation offered by service providers. As such, an efficient and successful professional,

scientific and technical services sector can contribute to the overall [competitiveness](#) of an economy.

Some professional and technical services are closely regulated by national governments and professional bodies, with restrictions on the number of entrants into the profession, rates charged and billing arrangements, organisational structure of businesses providing these services, exclusive rights enjoyed by practitioners, and the ability to advertise. The freedom to provide services and the freedom of establishment are central principles to the [internal market](#) for services. They guarantee EU enterprises the freedom to establish themselves in other Member States, and the freedom to provide services on the territory of another EU Member State. The [Directive on services in the internal market](#) (COM(2006) 123) aims to achieve a genuine internal market in services, removing legal and administrative barriers to the development of services activities between Member States. As well as covering many professional, scientific and technical services, the Directive applies to a wide variety of services including industrial and construction activities, as well as distributive trades, accommodation and food services, real estate, administrative and support service activities.

Table 4b: Key indicators, programming and broadcasting activities (NACE Division 60), 2009 - Source: Eurostat (sbs_na_1a_se_r2)

Main statistical findings

Structural profile

There were almost 12.1 thousand enterprises operating with programming and broadcasting (Division 60) as their main activity in the EU-27 in 2009. Together they employed 257 thousand persons, equivalent to 0.2% of the non-financial business economy (Sections B to J and L to N and Division 95) workforce and 4.5% of the information and communication services (Section J) workforce. EU-27 programming and broadcasting enterprises generated EUR 28100 million of value added which was a 0.5% share of the non-financial business economy total and a 5.9% share of the information and communication services total.

The apparent labour productivity of the EU-27's programming and broadcasting sector in 2009 was EUR 109.0 thousand per person employed, which was 2.6 times as high as the non-financial business economy average of EUR 41.6 thousand per person employed and also well above the information and communication services average of EUR 83.0 thousand per person employed. The relatively high level of apparent labour productivity for the EU-27's programming and broadcasting sector in 2009 meant that it ranked (according to this measure) as the ninth highest NACE division within the non-financial business economy.

Alongside high apparent labour productivity, average personnel costs for the EU-27's programming and broadcasting sector were also relatively high, at EUR 52.5 thousand per employee. Indeed, this was the seventh highest level of average personnel costs across all of the NACE divisions within the non-financial business economy and stood above the EUR 48.6 thousand per employee average for information and communication services and well above the EUR 30.0 thousand per employee average for the whole of the non-financial business economy.

Combining these two ratios, the wage-adjusted labour productivity ratio shows the extent to which value added per person employed covers average personnel costs per employee. Due to the high level of apparent labour productivity, the EU-27's programming and broadcasting sector had a high wage-adjusted labour productivity ratio, 210.3% in 2009, which was the ninth highest ratio among the NACE divisions that make-up the non-financial business economy, and well above the information and communication services average (171.2%) or the non-financial business economy average (138.8%).

The gross operating rate (the relation between the gross operating surplus and turnover) is a measure of operating profitability; it stood at 24.2% for the EU-27's programming and broadcasting sector in 2009 which was the ninth highest level of profitability (using this measure) among the NACE divisions within the non-financial business economy. It was also 2.5 times as high as the non-financial business economy average (9.7%) and higher than the information and communication services average (20.9%).

Sectoral analysis

The EU-27's programming and broadcasting sector may be divided into two constituent parts, the larger of which covers television-related activities (Group60.2), with the remainder of the sector made-up of radio-related activities (Group60.1). Television programming and broadcasting activities accounted for 81.3% of sectoral value added in 2009 and just under three quarters (72.6%) of the sectoral workforce. On the other hand, there was a higher number (7 thousand) of radio broadcasting enterprises; some 1.7 thousand more than were operating within television programming and broadcasting activities.

The high apparent labour productivity figure for the whole of the EU-27's programming and broadcasting sector was pulled upwards by the performance of television programming and broadcasting activities, where each person employed generated an average EUR130.0 thousand of added value in 2009. Although average personnel costs (EUR56.5 thousand per employee) were also relatively high, the combination of these two ratios led to a wage-adjusted labour productivity ratio of 230.6% for television programming and broadcasting activities. This was considerably higher than the corresponding value for radio broadcasting, where the EU-27's wage-adjusted labour productivity ratio was 159.0% in 2008.

For the gross operating rate, data is again only available for 2008 for radio broadcasting activities, when a rate of 19.7% was recorded for the EU-27. This was a relatively high value, but was still below the rate recorded for television programming and broadcasting activities (25.4% in 2009).

Country analysis

The United Kingdom reported the highest level of value added generated within the programming and broadcasting sector in 2009 (EUR6583 million); this equated to almost one quarter (23.4%) of the EU-27's sectoral added value. Germany had a similar level of value added (EUR6145 million), while the third and fourth largest contributions to EU-27 added value were made by Italy (EUR3742 million) and France (EUR3702 million). Together these four Member States generated 71.8% of the EU-27's total value added in the programming and broadcasting sector in 2009.

In relative terms, the programming and broadcasting sector contributed as much as 0.9% of national non-financial business economy value added in Poland in 2009; this share was just above that recorded in Cyprus and the United Kingdom (0.8%). At the other end of the range, the smallest contributions by the programming and broadcasting sector to non-financial business economy value added were made in Hungary, Slovenia and Slovakia (all shares of 0.1%).

The highest wage-adjusted labour productivity ratio in 2009 for the programming and broadcasting sector was recorded by the United Kingdom (498.7%); this figure was almost three times as high as the national average for the whole of the non-financial business economy. Poland and the Czech Republic also recorded relatively high wage-adjusted labour productivity ratios for the programming and broadcasting sector in 2009 (342.7% and 302.0%), which were 1.89 and 1.95 times as high as their national averages for the whole of the non-financial business economy.

There were six Member States with wage-adjusted labour productivity ratios for the programming and broadcasting sector below 100%. Among these, there were two Member States that stood out (with ratios below 90%); they were Luxembourg (54.5%) and Hungary (34.2%). Both of these Member States also recorded negative gross operating rates (-12.3% and -21.0%), as did Austria (-0.8%). At the other end of the scale, the highest gross operating rate for the programming and broadcasting sector was recorded by the United Kingdom (57.7% in 2009), which was 4.4 times as high as the national non-financial business economy average.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of

non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the programming and broadcasting sector in the EU, as covered by NACE Rev.2 Division60. This division includes the activities of creating content or acquiring the right to distribute content and subsequently broadcast that content, for radio, television and data programs of entertainment, news, talk, and the like. Also included is data broadcasting, typically integrated with radio or TV broadcasting. The broadcasting can be performed using different technologies, over-the-air, via satellite, via a cable network or via internet. This division also includes the production of programs that are typically narrowcast in nature (limited format, such as news, sports, education, and youth-oriented programming) on a subscription or fee basis, to a third party, for subsequent broadcasting to the public.

Radio broadcasting includes activities of broadcasting audio signals through radio broadcasting studios and facilities for the transmission of aural programming to the public, to affiliates or to subscribers. Also included are activities of radio networks (assembling and transmitting programming) and broadcasting over the internet.

Television programming and broadcasting activities include the activities of creating a complete television channel programme, from purchased or self-produced programme components or a combination thereof. The television channel can be either broadcast by the producing units or produced for transmission by a third party distributor, such as cable or satellite television providers. This activity includes video-on-demand channels.

This NACE division is composed of two groups:

- radio broadcasting (Group60.1);
- television programming and broadcasting activities (Group60.2).

Excluded are the production of television programme elements (movies, documentaries, talk shows, commercials and so on) not associated with broadcasting (Division59, part of [motion picture, video and television programme production, sound recording and music publishing activities](#)) and the assembly of a package of channels and distribution of that package, without programming (Division61, part of [telecommunications](#)), for example the distribution of cable and other subscription programming.

Table 4b: Key indicators, publishing activities (NACE Division 58), 2009 - Source: Eurostat (sbs_na_1a_se_r2)

Main statistical findings

Structural profile

There were around 90 thousand enterprises operating with publishing activities (Division 58) as their main activity in the EU-27 in 2009. Together they employed 960 thousand persons in 2008, equivalent to 0.7% of all persons employed in the non-financial business economy (Sections B to J and L to N and Division 95) and 16.6% of the information and communication services (Section J) workforce. They generated an estimated EUR 60 000 million of value added in 2008, which was equivalent to 11.9% of the information and communication services total.

The apparent labour productivity of the EU-27's publishing activities sector in 2009 was EUR 60 thousand per person employed, which was almost 50% higher than the non-financial business economy average of EUR 41.6 thousand per person employed. Nevertheless, productivity (using this measure) was relatively low in comparison with the whole of information and communication services, where apparent labour productivity averaged EUR 83 thousand per person employed.

Average personnel costs within the EU-27's publishing activities sector were, at EUR 42.0 thousand per employee in 2009, lower than the average for the whole of information and communication services (EUR 48.6 thousand per employee). However, as with apparent labour productivity, personnel costs per employee for publishing activities were above the non-financial business economy average (EUR 30.0 thousand per employee).

This pattern of apparent labour productivity and average personnel costs for the EU-27's publishing activities sector being somewhat above the non-financial business economy average but below the information and communication services average was continued for the wage-adjusted labour productivity ratio. This indicator combines the two previous measures and shows the extent to which value added per person employed covers average personnel costs per employee. EU-27 publishing activities had a wage-adjusted labour productivity ratio of 140.3% in 2008, only slightly higher than the non-financial business economy average of 138.8% in 2009 and well below the information and communication services average of more than 170% in both 2008 and 2009.

Sectoral analysis

Much has been written about the demise of the book publishing subsector in the face of competition from increasingly digitised media. However, almost three out of every ten enterprises within the EU-27's publishing

activities sector were classified with book publishing (Class58.11) as their main activity in 2009. The next highest number of enterprises was recorded for the more specialised activity of publishing journals and periodicals (Class58.14), with 23.0% of enterprises in the publishing sector. There was also a relatively high share (19.5%) for other software publishing enterprises (Class58.29); this latter activity excludes publishing computer games.

Turning attention to the breakdown of the publishing activities workforce: the picture was quite different, suggesting that the average size of enterprises varied considerably between subsectors. The largest employer was the publishing of newspapers (Class58.13), with an EU-27 workforce of 312.7 thousand in 2009, which equated to around one third of the total for publishing activities. Approximately one quarter of the sectoral workforce was composed of those employed within the publishing of journals and periodicals, while book publishing activities accounted for more than one in six of the sectoral workforce.

In output terms, the relative importance of the EU-27's publishing of newspapers subsector was somewhat lower than its share of employment. With EUR15747 million of added value in 2009, newspaper publishing accounted for just over one quarter of the total value added that was generated within the EU-27's publishing activities. This was only just ahead of the publishing of journals and periodicals (EUR14513 million), while other software publishing accounted for more than one fifth of sectoral added value and book publishing for around one sixth.

The relatively high apparent labour productivity for publishing activities was pulled upwards by other software publishing, where EU-27 value added reached EUR90 thousand per person employed in 2009. Aside from the relatively small other publishing subsector (Class58.19), which recorded apparent labour productivity of EUR31.0 thousand per person employed in 2009, each of the remaining publishing subsectors for which data are available recorded apparent labour productivity that was considerably above the non-financial business economy average (EUR41.6 thousand per person employed), ranging from EUR50 thousand per person employed to EUR62 thousand per person employed.

Across publishing activities, EU-27 average personnel costs per employee also rose to their highest level for other software publishing, peaking at EUR55.3 thousand per employee in 2009. As with apparent labour productivity, the only subsector to record personnel costs per employee below the non-financial business economy average (EUR30.0 thousand per employee) was the residual group of other publishing activities (EUR20.8 thousand per employee), while personnel costs per employee fell within the relatively narrow range of EUR38.8 thousand per employee to EUR42.3 thousand per employee across the remaining subsectors for which data are available.

Aside from the EU-27's publishing of newspapers subsector, which had a relatively low wage-adjusted labour productivity ratio (119.9% in 2009), most of the remaining publishing subsectors for which data are available recorded wage-adjusted labour productivity ratios that were slightly above the non-financial business economy average (138.8%), rising from 147.1% for the publishing of journals and periodicals to 163.2% for other software publishing. There was one exception to this pattern, as the publishing of directories and mailing lists (Class58.12) recorded a wage-adjusted labour productivity ratio that was much higher, reaching 300.0% in 2008.

While there is no information available for the whole of the EU-27 publishing activities sector for the [gross operating rate](#), there is a limited amount of data for five subsectors. Among these, EU-27 gross operating rates in 2009 were generally much higher than the non-financial business economy average (9.7%), ranging from 13.9% for book publishing to 34.5% for the publishing of directories and mailing lists. The only exception to this pattern was the publishing of newspapers, where the EU-27 gross operating rate stood at 7.0% in 2009.

Country analysis

Germany had the highest level of value added among the EU Member States within the publishing activities sector in 2009, at EUR11925 million. The United Kingdom and France were also relatively important players within the publishing activities sector, as they recorded added value of EUR10740 million and EUR9946 million, which was almost three times as high as the next country – Italy (EUR3401 million). As such, the three largest Member States accounted for more than 60% of the total value added generated by the 25 Member States for which data are available (no data for Greece or Malta; Danish data is for 2008).

In value added terms, Finland was the most specialised in the publishing activities sector in 2009, generating 1.6% of its non-financial business economy value added in this sector. Denmark, Sweden, the United

Kingdom, France and the Netherlands were the only other Member States to report that upwards of 1% of their non-financial business economy value added was generated by publishing activities. At the other end of the scale, the relative importance of publishing activities was at its lowest in Bulgaria, Cyprus, Romania and Slovakia, where this sector accounted for 0.5% of non-financial business economy added value.

At a more detailed level, the United Kingdom had the highest share of EU-27 value added for book publishing, publishing of journals and periodicals (where it was also the most specialised Member State), and other publishing activities. These figures may be influenced to some extent by the prominent position of the English language. On the other hand, France recorded the highest shares of EU-27 value added for computer games and for other software publishing (where it was also the most specialised Member State). Germany accounted for one third of the EU-27's value added for the publishing of newspapers.

Most Member States reported wage-adjusted labour productivity ratios for publishing activities in 2009 that were below their national averages for the whole of the non-financial business economy. This was particularly true in Romania, Bulgaria, the [Baltic Member States](#) and the Czech Republic, although Slovenia and Sweden were the only Member States to record wage-adjusted labour productivity ratios that were below 100% – with the average added value generated by each person employed not covering average personnel costs. The highest wage-adjusted labour productivity ratio in this sector was recorded in Slovakia (180.8%), followed by Germany (166.5%) and the United Kingdom (165.1%). Slovakia and Germany, together with the Netherlands and Finland, were the only four Member States (among those for which data are available) to report wage-adjusted labour productivity ratios for publishing activities that were above those for the non-financial business economy as a whole.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the publishing activities sector in the EU, as covered by NACE Rev.2 Division58. This division includes activities such as the publishing of books, periodicals and software, as well as other publishing activities. The output of the publishing activities sector is characterised by the intellectual creativity required in its development and many of the products that are made within this sector are protected by copyright.

Book publishing includes publishing in print, electronic (CD, electronic displays and so on) or audio form or on the internet. The publishing of directories and mailing lists includes the publishing of lists of facts/information that are protected in their form, but not in their content. The publishing of newspapers includes the activities of publishing newspapers, including advertising newspapers, appearing at least four times a week. The publishing of journals and periodicals includes the activities of publishing periodicals and other journals, appearing less than four times a week. Directories and mailing lists, newspapers, journals and periodicals can be published in print or electronic form, including on the internet. Other publishing activities include publishing (including on-line) of catalogues, photos, engravings and postcards, greeting cards, forms, posters, reproduction of works of art, advertising material and other printed matter, on-line publishing of statistics and other information.

The publishing of computer games includes games for all platforms. Other software publishing includes publishing of ready-made (non-customised) software, including translation or adaptation of non-customised software for a particular market on own account.

This NACE division is composed of seven classes organised into two groups:

- book publishing (Class58.11);

- publishing of directories and mailing lists (Class58.12);
- publishing of newspapers (Class58.13);
- publishing of journals and periodicals (Class58.14);
- other publishing activities (Class58.19);
- publishing of computer games (Class58.21);
- other software publishing (Class58.29).

This division excludes publishing of motion pictures, videotapes and movies on DVD or similar media, of music and sheet books and the production of master copies for records or audio material (Division59, part of the [motion picture, video and television programme production, sound recording and music publishing activities sector](#)). It also excludes [printing and the reproduction of recorded media](#) (Division18), as well as the retail sale of non-customised software (Division47, which forms part of [retail trade](#)), the production of software not associated with publishing, including translation or adaptation of non-customised software for a particular market on a fee or contract basis (Division62, part of [computer programming, consultancy and related activities](#)), and the on-line provision of software (Division63, part of [information service activities](#)).

Publishing statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers publishing statistics, corresponding to NACE Group 22.1, which is part of the [media and communications](#) sector. The activities covered in this article are the producing and issuing of informative material, including the publishing of both:

- printed matter;
- music.

Figure 1: Publishing (NACE Group 22.1). Relative weight within publishing, EU-27, 2006 (%) (1)

Table 1: Publishing (NACE Group 22.1). Structural profile: ranking of top five Member States in terms of value added and persons employed, 2006

Value added generated by the 81.0 thousand [enterprises](#) that make up the [EU-27](#)'s publishing sector (NACE Group 22.1) reached EUR 49 billion in 2006, derived from [turnover](#) of EUR 130 billion. This was equivalent to 14.0% of the media and communications (NACE Divisions 22 and 64) value added, and 16.4% of its turnover. There were approximately 800.0 thousand persons [employed](#) in these activities in the EU-27, which represented 16.5% of the media and communications workforce. Within the publishing subsector the largest contribution to value added in the EU-27 in 2006 was from the publishing of newspapers (NACE Class 22.12), followed by the publishing of journals and periodicals (NACE Class 22.13) and the publishing of books (NACE Class 22.11). Slightly more than one quarter of the EU-27's value added in the publishing sector in 2006 was concentrated in the United Kingdom while one fifth came from Germany. Unsurprisingly, the United Kingdom ranked as one of the most specialised Member States within the publishing sector in value added terms, as this activity generated 1.2% of its [non-financial business economy](#) value added, lower only than in Finland.

Expenditure and productivity

The [investment rate](#) in publishing was particularly low, just 5.5% in the EU-27, one of the lowest of all non-financial business economy NACE groups in 2006. Apparent [labour productivity](#) for the EU-27's publishing sector was below the media and communications average in 2006, while average [personnel costs](#) were above average. This situation led to a [wage-adjusted labour productivity ratio](#) (158.1%) for the publishing sector that was well below the media and communications average (195.0%), but nevertheless still above the average ratio for the non-financial business economy.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Context

This sector gathers together several activities linked to media and communication activities, however, within this group a distinction has to be made between traditional activities (for example, postal services) for which the level of activity is rather stable and other newer activities (such as mobile telephony and electronic publishing), for which growth developments are more marked.

While the Internet was initially seen by many as a direct competitor to printed matter, enterprises that traditionally published printed media have often diversified into online media too, for example, newspapers, magazines, books or reference material are increasingly consulted online or through some other type of electronic medium. Note that on-line publishing, not in connection with other publishing, is considered as a computer and related activity rather than publishing.

Pulp, paper and paper product statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). The present article covers the pulp, paper and paper products sector, corresponding to [NACE Rev 1.1 Division 21](#), which is part of the [wood and paper manufacturing](#) sector. The activities covered in this article are:

- the manufacture of pulp, paper and paperboard, through mechanical and chemical processes, corresponding to NACE Group 21.1;
- further processing of pulp, paper and paperboard, which includes the manufacture of corrugated, household and sanitary paper products, as well as newsprint, wallpaper and stationery (NACE Group 21.2).

The pulp, paper and paper products sector does not include forestry, logging and related activities (NACE Division 02), and so these are not covered in this article.

Table 4: Manufacture of pulp, paper and paper products (NACE Division 21). Main indicators, 2006 (1).

The pulp, paper and paper products (NACE Division 21) manufacturing sector was dominated by a relatively few number of **large enterprises**; there were only 19.4 thousand **enterprises** across the **EU-27** that had pulp, paper and paper products manufacturing as their main activity in 2006, together they **employed** an estimated 715.0 thousand persons and generated EUR 41.1 billion of **value added**, which was equivalent to 52.5% of the total value added generated across the whole of the wood and paper manufacturing sector.

The manufacturing of articles of paper and paperboard (NACE Group 21.2) subsector was larger than the manufacturing of pulp, paper and paperboard (NACE Group 21.1) subsector, both in terms of value added generated (55.6% of the pulp, paper and paperboard total) and, more particularly, of employment (68.7%). The manufacture of corrugated paper and paperboard and of containers of paper and paperboard (NACE Class 21.21) was the main activity among those covered by the manufacture of articles of paper and paperboard, accounting for more than 50% of its value added and employment. The manufacture of paper and paperboard (NACE Class 21.12) was the principal activity among those within the pulp, paper and paperboard (NACE Group 21.1) manufacturing subsector, accounting for the overwhelming share of value added and employment.

The value added generated by the pulp, paper and paper products manufacturing sector in Germany was EUR 9.7 billion in 2006, which equated to 23.7% of the EU-27's value added. This was more than twice the contribution made by Italy or France, the next largest Member States within this activity. However, in terms of the relative contribution made by pulp, paper and paper products to the overall value added of the **non-**

[financial business economy](#) , it was Sweden and Finland that were by far the most specialised producers; the sector contributed 2.3% of Swedish value added in the non-financial business economy, which was three times as high as the EU-27 average, while in Finland its share of non-financial business economy value added rose to 4.3%, which was six times as high as the EU-27 average.

Between 1997 and 2007, there were upward trends in EU-27 output of pulp, paper and paper board (with [production](#) rising by an average of 2.1% per year) and articles of paper and paper board (1.5% per year). At a more detailed level, there was a relatively uniform and upward evolution (growth of 2.5% per year on average) for the manufacture of household and sanitary goods and of toilet requisites (NACE Class 21.22), which contrasted sharply with a relatively unchanged evolution of output observed for paper stationery (-0.2% per year).

Expenditure and profitability

[Personnel costs](#) in the pulp, paper and paper products manufacturing sector accounted for 17.1% of total operating expenditure across the EU-27 in 2006, a slightly lower proportion than for the whole of the wood and paper manufacturing sector (17.9%). Average personnel costs in the pulp, paper and paper products manufacturing sector, however, were relatively high at EUR 37.7 thousand per employee in 2006. This was particularly the case with respect to the pulp, paper and paperboard subsector, where average personnel costs were EUR 46.1 thousand per employee, while personnel costs accounted for a relatively low share of operating expenditure (14.2%), suggesting a relatively high-wage, but capital-intensive manufacturing activity.

The apparent [labour productivity](#) of the EU-27's pulp, paper and paper products manufacturing sector was EUR 57.5 thousand per person employed in 2006. In more detail, the apparent labour productivity of the pulp, paper and paperboard subsector reached EUR 81.3 thousand per person employed in 2006, which was well above that registered for the articles of paper and paperboard subsector (EUR 47.6 thousand per person employed). Even when taking into account the differences in wages, the productivity of the subsectors remained wide apart; as the wage-adjusted labour productivity ratio for the pulp, paper and paperboard subsector was 176.2% in 2006, compared with 138.9% for the articles of paper and paperboard subsector.

Among the Member States, the highest wage-adjusted labour productivity ratios for the pulp, paper and paper products manufacturing sector were recorded by Slovakia (282.1%), Poland (278.7% in 2005) and Portugal (264.2%).

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include the [PRODCOM](#) statistics on the production of manufactured goods.

Context

The multi-functional role of forests is an area of increasing global scrutiny. Wood is an important, renewable economic resource, while forests are increasingly recognised for the environmental role they play in climate regulation, biodiversity, air, soil and water quality, as well as their recreational function.

Building on the EU Forest Action Plan ([COM\(2006\) 302 final](#)) for 2007 to 2011 and its 18 key actions for sustainable forest management and the improved long-term competitiveness of its associated industries, the EU has been active in pushing for international commitment to end global forest cover loss by 2030 as part of a new 'forestry package'. This package includes proposals from the [European Commission](#) that look to address some of the challenges of deforestation and forest degradation in order to tackle climate change and biodiversity loss ([COM\(2008\) 645 final](#)), as well as laying down obligations for operators who place timber and timber products on the market ([COM\(2008\) 644 final](#)). These would include obliging market traders to certify that the timber and timber products they sell have been harvested according to the relevant laws of

the country of origin. It is also proposed that a new global financial fund, known as the Global Forest Carbon Mechanism (GFCM), be made available to developing countries as a reward for emissions reductions achieved by taking action to reduce deforestation and forest degradation. The EU's [Emissions trading system \(ETS\)](#) would be a major source of funding for any GFCM, whereby EUR 2.5 billion could be provided to the fund by 2020 through 5% of auctioning revenues. Furthermore, those governments that sign-up to a global climate change deal could also be allowed to use so-called deforestation credits towards their individual CO₂ reduction commitments.

These proposals, as well as an EU Forest Action plan could have implications for the diverse wood and paper manufacturing sector in the EU. In part, this may reflect the varied size structure of enterprises within the two subsectors: the pulp, paper and paper products subsector is dominated by large, multinational enterprises, many of which are in the Nordic Member States; whereas, the wood and wood products subsector is characterised by relatively small-scale enterprises that are predominantly privately-owned and serve local or national markets.

Pulp is the basic material for the manufacture of paper and board and can be made from woodchips (a by-product of sawmills), fresh wood, recovered paper and from some agricultural products (natural textiles or industrial crops). However, it is in the use of recycled fibres that much progress has been made: the principle is that recycling helps keep the sourcing of virgin fibres at volumes where forests can be managed sustainably, as well as keeping recoverable materials out of landfill. The [European Parliament and Council Directive on packaging and packaging waste of 1994](#) set relatively broad recycling targets for packaging by the end of 2008. The European Commission is currently in the process of making a new set of target proposals for packaging and packaging waste, which should cover the period 2009 to 2014.

The European Declaration on Paper Recycling is an industry initiative that has set a specific target for the recycling rate at 66% of all paper and board products consumed in Europe to be achieved by 2010. The [European Recovered Paper Association \(ERPA\)](#) reported that the recycling rate for 2006 had reached 63.4%, with 58.2 million tonnes of paper and board having been recycled (marking an overall increase of about 10% since 2004) in the EU-27, Switzerland and Norway. The [European Recovered Paper Identification System](#) is a further industry initiative that was launched by the Confederation of European Paper Industries (CEPI) in October 2008 to promote a more consistent quality and grade of every bale of recovered paper by means of identification that will enable full traceability.

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers manufacture of radio, television and communication equipment, corresponding to NACE Division 32, which is part of the [electrical machinery and optical equipment](#) sector. The activities covered in this article are:

- electronic components, including active, passive and printed circuit boards (PCBs), corresponding to NACE Group 32.1;
- television cameras, transmission apparatus for radio and television, telephonic switching apparatus (including LANs and modems), telephones and fax machines, corresponding to NACE Group 32.2; (note that information, communication and media content that makes use of this equipment is dealt with in the article on [Media and communications statistics - NACE Rev. 1.1](#));
- audio-visual equipment and related appliances, which includes as loudspeakers, headphones and aerials, and of other electronic consumer appliances, which includes telephone answering machines, corresponding to NACE Group 32.3.

	Enterprises (thousand)	Turnover (EUR million)	Value added (EUR million)	Persons employed (thousand)	Share in total (%)

Source: Eurostat / SBI

Table 4: Manufacture of radio, television and communication equipment and apparatus (NACE Division 32). Main indicators, 2006 (1)

Just over a quarter (25.6%) of the value added generated within the EU-27's electrical machinery and optical equipment (NACE Subsection DL) manufacturing activities in 2006 came from the manufacture of radio, television and communication equipment (NACE Division 32) sector. The EUR 51.8 billion of value added that was generated in the EU-27 by 29.4 thousand enterprises that reported radio, television and communication equipment manufacturing as their principal activity in 2006, represented just 14.5% of the total number of enterprises within the electrical machinery and optical equipment total. The radio, television and communication equipment sector employed 771.6 thousand persons in 2005.

Due to scarce data availability, the most complete measure of the relative importance of the subsectors that compose the EU-27's radio, television and communication equipment sector is presented in terms of employment shares. The manufacture of electronic valves and tubes and other electric components (NACE Group 32.1) was the largest subsector, employing 309.9 thousand persons in 2006 (40.9% of the radio, television and communication equipment manufacturing total), which was only slightly more than the 36.9% share recorded for television and radio transmitters and apparatus for line telephony and line telegraphy manufacturing (NACE Group 32.2), with the remainder of the workforce (22.2% in 2005) employed within the manufacture of television and radio receivers, sound or video recording and reproducing apparatus (NACE Group 32.3).

Just over a fifth (20.9%) of the value added generated by the EU-27's radio, television and communication equipment sector came from Germany in 2006, while there were two other Member States that recorded a double digit share of EU-27 value added – namely, France (13.4%) and Finland (11.2%). Finland was by far the most specialised Member State for the manufacture of radio, television and communication equipment (largely due to mobile telephony), as this sector accounted for 7.0% of its non-financial business economy value added (compared with an EU-27 average of 0.9%). The specialisation ratio for Finland was approximately double that recorded in the second most specialised country, Hungary (3.6%), while Ireland and Sweden were also relatively specialised.

The development of the EU-27 production index for the manufacture of radio, television and communication equipment in the ten years between 1997 and 2007 followed a similar but slightly more amplified development when compared with the production index for the whole of electrical machinery and optical equipment manufacturing. The index of production for radio, television and communication equipment manufacturing followed a very cyclical pattern, with average growth of 7.5% per year during the period 2002 to 2007, following on from average losses of 5.6% per year between 2000 and 2002. Despite the fluctuations in output, the overall expansion in EU-27 output of radio, television and communication equipment manufacturing between 1997 and 2007 outstripped all other industrial (NACE Sections C to E) divisions for which data are available, averaging 5.4% per year over the ten-year period.

Expenditure and productivity

Gross [tangible investment](#) made by the EU-27's radio, television and communication equipment manufacturing sector in 2006 was valued at EUR 7.8 billion, which was 0.8% of the non-financial business economy total. The [investment rate](#) of the radio, television and communication equipment manufacturing sector was 15.1%, slightly below the non-financial business economy average of 18.4%, but relatively high for one of the electrical machinery and optical equipment sectors. Among the Member States¹⁰⁴, the investment rate for the radio, television and communication equipment manufacturing sector climbed to over 20% in ten of the Member States in 2005 or 2006. However, the investment rate of the radio, television and communication equipment manufacturing sector was only above the non-financial business economy average in four of the Member States for which data are available. Among these, Germany (77% above average) clearly stood out, while the Czech Republic, Poland (2005) and Italy (22% to 14% higher) also reported relatively high investment rates for radio, television and communication equipment manufacturing.

The structure of [operating expenditure](#) within the radio, television and communication equipment manufacturing sector was such that [personnel costs](#) accounted for 15.4% of the total, the remainder being made up of purchases of goods and services. This share was lower than the average proportion of operating expenditure accounted for by personnel costs within the whole of the electrical and optical equipment sector (20.6%), despite the fact that average personnel costs were EUR 43.3 thousand per employee – the highest level among the four NACE divisions in the electrical machinery and optical equipment sector. In a similar vein, apparent [labour productivity](#) was also relatively high for the EU-27's radio, television and communication equipment manufacturing sector (EUR 62.5 thousand per person employed in 2005). Nevertheless, when productivity was adjusted to take account of personnel costs, the [wage-adjusted labour productivity ratio](#) for the EU-27's radio, television and communication equipment manufacturing sector was 143.1% in 2005, above the average for the whole of electrical and optical equipment (130.9%) in the same year, but still slightly below the non-financial business economy average (146.5%) in the same year.

The most productive workforce among the Member States¹⁰⁵ for radio, television and communication equipment manufacturing was in Ireland, where each person employed generated an average of EUR 318.9 thousand of added value in 2006. The respective workforces of Finland and Sweden were also highly productive (EUR 164.6 thousand and EUR 144.7 thousand per person employed). These figures, to some degree reflect the relatively high average levels of productivity in these three economies – although it is also interesting to note that all three countries were among the most specialised Member States in terms of the manufacture of radio, television and communication equipment. Furthermore, when comparing the labour productivity of the radio, television and communication equipment manufacturing sector with national non-financial business economy averages, Ireland again topped the ranking – as its workforce for this sector was 3.8 times as productive as the non-financial business economy average. Finland (2.5 times) and Sweden (2.4 times) were joined by Portugal and Bulgaria (both 2005) as the only other Member States where the radio, television and communication equipment workforce was at least twice as productive as the national non-financial business economy average.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include [short-term statistics \(STS\)](#) and the [PRODCOM](#) statistics on the production of manufactured goods.

¹⁰⁴Poland and Portugal, 2005; Luxembourg, Malta and the Netherlands, not available.

¹⁰⁵Bulgaria, Cyprus, Poland, Portugal and Romania, 2005; Luxembourg, Malta and the Netherlands, not available.

Context

The electrical machinery and optical equipment sector is an important and strategic part of Europe's manufacturing sector, producing a wide range of mostly high-technology products (for example, computers, switchgears or semi-conductors). This sector has been cited as being at the centre of industrial development, as almost every other sector depends, at least to some degree, on the capital equipment, technology, end-products, research and innovations that are provided by the electrical machinery and optical equipment sector. It is therefore often referred to as one of the main drivers of [productivity](#) gains and central to the EU's objective of creating more and better jobs.

The goods and services made within the electrical machinery and optical equipment sector range from capital goods used in energy and primary transformation activities, transport manufacturing (motor vehicles, aeronautics and rail equipment producers) or process manufacturing sectors (agro-industries, chemicals, plastics or wood), through intermediate goods (such as electronic components or wiring) that are often used by other manufacturers, to consumer goods (such as consumer electronics, mobile phones and household appliances).

This sector operates within a long-established legislative framework that covers issues such as product safety, energy labelling, minimum efficiency requirements, eco-design and waste. Two Directives ([2008/34](#) and [2008/35](#)) on waste electrical and electronic equipment (WEEE) and the restriction of the use of certain hazardous substances in electrical and electronic equipment were introduced in 2008. The EU aims to take measures to prevent the generation of electrical and electronic waste and to promote reuse, recycling and other forms of recovery in order to reduce the quantity of such waste by encouraging manufacturers to design products with the environmental impacts in mind throughout their entire life cycle.

The potential role that may be played by the electrical machinery and optical equipment sector with respect to energy efficiency has also been highlighted in recent years. Indeed, considerable effort has gone into reducing the energy consumption of appliances, although changes in lifestyle and working practices have sometimes offset these, for example, while changes to the manufacture of domestic and office appliances has made these more energy efficient, rising equipment rates and the introduction of new technologies may result in higher overall energy consumption. Several directives cover this area of energy saving, in particular a Directive on eco-design requirements for energy-using products, a Directive on the energy labelling of domestic appliances and a Regulation on the energy efficiency labelling programme for office equipment.

The main downstream customers for manufacturers of electronic components include the computer and office equipment sector, communications manufacturers, as well as motor vehicles manufacturing and manufacturers of consumer electronics/household appliances, with electronic components forming the technology backbone on which PCs, wireless handsets, navigation and ABS systems, set-top boxes and camcorders are based. Technological innovation has led to miniaturisation, digitalisation and convergence in terms of radio, television and communication equipment, as witnessed through multifunctional, digital products (such as third generation mobile phones that incorporate high-speed Internet access and video telephony, or MP3 players that can also be used to surf the Internet, or view photographs).

This area of the economy is highly intensive in terms of [research and development \(R & D\)](#) , underlining its important role as a driver for innovation. Much of the research is conducted in knowledge-based clusters that are centred on the proximity of universities, research and design centres and manufacturing facilities, such as Dresden (Germany), Dublin (Ireland), Grenoble (France), Catania (Italy), the Nijmegen-Eindhoven-Leuven axis (Netherlands/Belgium) or around Helsinki (Finland).

In this context, the seventh Framework Programme (FP7) on research and development may provide a platform to share ideas and innovate. Among the technology platforms established for this purpose are the networked and electronic media platform which looks to focus on generalised broadband access, increased mobility, the availability of richer media formats and contents, as well as new home networks and communications platforms, and the mobile and wireless communications technology platform that looks to build on GSM and [DECT technologies](#) .

The radio, television and communication equipment sector faces intense competition from the Far East, which further underlines the need for European manufacturers to continually innovate. At the same time, many product markets are characterised by imitation and it is often difficult to protect [intellectual property](#) .

Notes

Rail transport statistics - NACE Rev. 1.1

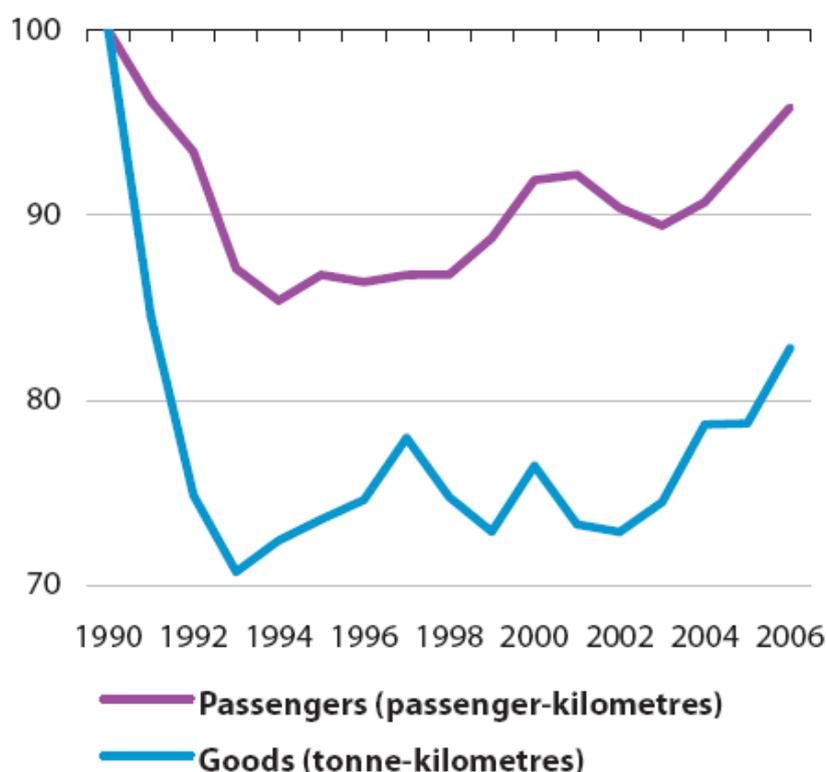

Data from January 2009. Most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers rail transport statistics, corresponding to NACE Group 60.1, which is part of the [transport and storage](#) sector. The activities covered in this article are the transport by railways of:

- passengers;
- goods.

This article does not cover:

- activities relating to the operation of the rail infrastructure, which are classified as auxiliary transport activities and are covered by the article on [Warehousing and transport logistics statistics - NACE Rev. 1.1](#) ;
- urban and suburban rail transport of passengers, which is included in the article on [Road and other land transport statistics - NACE Rev. 1.1](#) .

Source: Eurostat, ITF, UIC, national statistics, estimates, in EU energy and transport in figures statistical pocketbook 2007/2008, European Commission, Directorate-General for Energy and Transport

Figure 1: Rail transport. Evolution of rail transport, EU-27 (1990=100)

Main statistical findings

Structural profile

Value added in the EU-27's rail transport (NACE Group 60.1) sector reached EUR 31.9 billion in 2005, equivalent to 8.4% of the transport services (NACE Divisions 60 to 63) total. In the EU-27, there were 0.8 thousand **enterprises** in this sector with a total of 880.7 thousand persons employed (2005), equivalent to 10.1% of the EU-27's transport services workforce. Although data availability among the Member States is weak in this sector, it is clear that the rail transport sector is particularly important in Hungary and Luxembourg, as this sector accounted for 2.0% and 1.8% respectively of national **non-financial business economy** value added in 2006, more than three times the 0.6% (2005) share for the EU-27 as a whole.

Transport of goods and passengers

The development of EU-27 goods and passenger rail transport between 1990 and 2006 shows a significant change: passenger transport volumes reached a low in 1994, after which average growth was 1.0% per year; goods transport volumes stabilised in 1993 after which average growth was 1.2% per year. Growth was particularly strong in the last three years for which data are available, passenger transport increasing by an average of 2.3% per year between 2003 and 2006, and goods transport by an average of 3.6% over the same period.

Expenditure and productivity

Personnel costs accounted for 38.6% of rail transport **operating expenditure** in the EU-27 in 2005, the highest share among transport services activities (among the transport and storage sub-sectors) and more than double the average share for the non-financial business economy. Average personnel costs reached EUR 30.4 thousand per employee in 2005, in line with the transport services average, while apparent **labour productivity** of EUR 36.2 thousand per person employed was well below the average. The resulting **wage-adjusted labour productivity ratio** in the EU-27 was 118.9% for the rail transport sector in 2005, some way below the 141.9% average for all transport services in the same year.

Data sources and availability

Eurostat, ITF, UIC, national statistics, estimates, in EU energy and transport in figures statistical pocketbook 2007/2008, [European Commission](#), Directorate-General for Energy and Transport.

Structural change – rail transport services and infrastructure

In **structural business statistics (SBS)**, enterprises are classified according to their principal activity. An enterprise that is simultaneously a rail service operator and a rail infrastructure operator would often be classified in the rail transport activity (NACE Group 60.1), assuming that the rail service operation part is the larger of the two activities. If such an enterprise is split into two separate enterprises (as has happened in some countries), only the rail transport enterprise would stay classified to NACE Group 60.1, and the rail infrastructure operator would be classified to supporting land transport activities (NACE Class 63.21) – this in part explains some of the large changes in employment in the rail transport sector seen in recent years.

Context

The transport and storage sector focuses on transport services provided to clients for hire and reward. When analysing transport traffic volumes (for example, tonnes of freight) as presented in this article, it is important to bear in mind that these include own account transport as well as transport services for hire and reward. This is particularly important in road transport where, for example, a manufacturer might collect materials or deliver own **output**, rather than contracting a transport service enterprise to do this. Equally, the use of own vehicles (typically passenger cars) accounts for a very large part of passenger transport. Such own account transport does not contribute towards the statistics on the transport services sector.

EU transport policy is based upon the [2001 White paper 'European transport policy for 2010: time to decide'](#) and the 2006 mid-term review in the European Commission's communication ([COM\(2006\) 314](#))'Keep Europe moving – sustainable mobility for our continent'. In 2007 the European Commission adopted a communication ([COM\(2007\) 606](#)) on 'Keeping freight moving', to make rail freight more competitive, facilitate modernisation of ports, and review progress in the development of sea shipping.

Environmental issues remain of great importance to this sector, as transport is a major source of emissions and noise. In 2008 the European Commission put forward a package of measures related to road and rail transport referred to as 'Greening Transport'. This included a communication ([COM\(2008\) 433](#)) summarising the packages and initiatives planned for 2009, a strategy to internalise the cost of transport externalities, a proposal for a Directive on road tolls for lorries, and a communication on rail noise. The overall thrust of the package is to try to move towards more sustainable transport.

Considerable legislative efforts have been made to open up and revitalise the rail transport sector, motivated in part by the wish to take advantage of lower emissions from rail transport, and to reduce road congestion. Both national and international rail freight networks have been open since the beginning of 2007, and international passenger transport will be open from January 2010. Further legislative measures since 2001 have concerned improving network interoperability and safety, and laying down passenger rights and obligations. In December 2008 the European Commission adopted a proposal for a Regulation of the [European Parliament](#) and of the [Council](#) ([COM\(2008\) 852](#)) to support a competitive freight network, essentially to increase the speed of rail freight.

Railway equipment production statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers railway equipment production, corresponding to NACE Group 35.2, which is part of the [transport equipment](#) sector. The activities covered in this article are the manufacture of:

- railway locomotives and rolling stock;
- tramway locomotives and rolling stock.

	Highest value added (1)		Largest number of persons employed (2)		Most specialised: share in non-financial business economy (%) (3)			
	Country	(EUR million)	(% of EU-27)	Country	(thousand)	(% of EU-27)	Country	Value added

Source: Eurostat (PROD/COM)

Table 2: Railway equipment (CPA Group 35.2). Production of selected products, EU-27, 2007 (1)

Value added generated by the 1.1 thousand [enterprises](#) classified to railway and tramway locomotives and rolling stock manufacturing (NACE Group 35.2) in the [EU-27](#) was EUR 7.1 billion in 2006, equivalent to a 3.6% share of the transport equipment manufacturing (NACE Subsection DM) total. The workforce in this sector numbered 164.8 thousand persons, equivalent to 5.2% of the transport equipment manufacturing workforce.

Slightly more than one quarter of the EU-27's [value added](#) was accounted for by Germany (26.7%), followed by France, the United Kingdom and Spain each with more than 10% of the EU-27 total. The workforces in this sector in Romania and Poland were the second and third largest within the EU-27, smaller only than in Germany. Romania was particularly specialised in railway and tramway locomotives and rolling stock manufacturing, as this sector contributed 0.5% of total value added within the Romanian [non-financial business economy](#) in 2005, a share that was more than four times as high as the EU-27 average.

Railway and tramway locomotives and rolling stock manufacturing saw [output](#) in the EU-27 fall sharply in

2000, since when output expanded most years. Average output growth between 2000 and 2007 was 2.3% per year, boosted by strong growth in 2002 and most recently in 2007.

Expenditure and productivity

In 2006 gross [tangible investment](#) in the EU-27's railway and tramway locomotives and rolling stock manufacturing sector was equivalent to 6.6% of value added, giving this sector the lowest [investment rate](#) among the subsectors of transport equipment production. The labour-intensive nature of this activity was reinforced by the high proportion of [operating expenditure](#) devoted to [personnel costs](#) which was 24.2% compared with a transport equipment manufacturing average of 15.9%. Average personnel costs in the EU-27's railway and tramway locomotives and rolling stock manufacturing sector were EUR 31.8 thousand per employee, above the non-financial business economy average, while apparent [labour productivity](#) was EUR 42.8 thousand per person employed, below the non-financial business economy average. The EU-27 [wage-adjusted labour productivity ratio](#) of 134.4% was in line with the transport equipment manufacturing average (133.3%), and therefore well below the non-financial business economy average (151.1%). Slovakia and Portugal (2005) both recorded low wage-adjusted labour productivity ratios in this sector, while Spain was the only Member State¹⁰⁶; to record a wage-adjusted labour productivity ratio in this sector above its average for the non-financial business economy.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include the [PRODCOM](#) statistics on the production of manufactured goods.

Context

The transport equipment manufacturing sector is central to economic development, as it provides the means for transporting both individuals and goods. Demand for transport equipment has risen as the volume of goods transported and the distance travelled by passengers have expanded greatly – see the article on [Transport and storage statistics] for information on transport flows.

The issue of sustainable development is likely to play an important role in future product developments, as transport equipment manufacturers try to meet demands for more environmentally friendly transport solutions, for example, engines with lower fuel consumption or emissions.

Most transport equipment manufacturing activities are structured on the basis of complex pyramidal relationships between major manufacturers and several tiers of component suppliers, ranging from systems suppliers down to very small, specialised manufacturers that may provide a single component for a vehicle. It is common to find clusters of enterprises concentrated in regions around the leading producers.

Notes

Real estate activity statistics - NACE Rev. 2

Data from April 2012, most recent data: Further Eurostat information, Main tables and Database

This article presents an overview of statistics for the [European Union's \(EU's\)](#) real estate sector, as covered by [NACE Rev. 2 Section L](#). Real estate services are provided to households and to business clients. The use of renting can increase financial flexibility, reducing the need to commit own capital. Real estate activities are divided into three separate NACE groups and include:

- buying and selling own real estate (Group 68.1);
- renting (to third parties) and operating own or leased residential and non-residential real estate, including both furnished and unfurnished property; the development of building projects for own operation is also included (Group 68.2);
- appraising real estate; providing real estate agency services as an intermediary; managing property as an agent (Group 68.3).

Real estate activities do not include facilities management which is considered part of [administrative and support services](#) (Section M), nor the development of building projects for later sale which is part of [construction](#) (Section F), nor short-stay letting of accommodation (for example, for holiday purposes) which is part of [accommodation and food services](#) (Section I).

Table 4b: Key indicators, real estate activities (NACE Section L), 2009 - Source: Eurostat (sbs_na_1a_se_r2)

Main statistical findings

Structural profile

Around one in every 20 enterprises within the EU-27's non-financial business economy (Sections B to J and L to N and Division 95) operated within real estate activities (Section L) in 2009, a total of almost 1.1 million enterprises. Together they employed 2.6 million persons, equivalent to 1.9% of the non-financial business economy workforce, while they generated EUR 216 000 million of value added which was 3.9% of the non-financial business economy total. As its focal point is on land and property, the real estate activities sector is clearly a capital-intensive activity and displays particularly high levels of tangible investment.

As a consequence of the different shares of real estate activities in employment and value added terms, the apparent labour productivity of this sector was particularly high, averaging EUR 83 thousand per person employed across the EU-27 in 2009, the same as for information and communication services (Section J); the joint

third highest apparent labour productivity among the non-financial business economy NACE sections. In contrast, **average personnel costs** were EUR 29.7 thousand per employee in the real estate activities sector, which was almost identical to the non-financial business economy average of EUR 30 thousand per employee. The **wage-adjusted labour productivity ratio** combines the two previous indicators and shows the extent to which value added per person employed covers average personnel costs per employee. Due to high labour productivity and modest average personnel costs the EU-27's real estate activities sector in 2009 had the third highest wage-adjusted labour productivity ratio among the non-financial business economy NACE sections, reaching 278.6%. The **gross operating rate** (the relation between the **gross operating surplus** and **turnover**) was also extremely high, as the gross operating surplus was equivalent to 40.3% of turnover, which was more than four times the non-financial business economy average (9.7%) and the highest rate among the non-financial business economy NACE sections. Both the wage-adjusted labour productivity ratio and the gross operating rate are influenced by the fact that purchases of goods and services as well as personnel costs in this activity are often small in comparison with the depreciation or financial expenditure which is typically higher in capital-intensive activities such as buying and selling or renting of own property.

Sectoral analysis

The largest subsector within the EU-27's real estate activities sector was renting and operating of real estate (Group 68.2) which accounted for nearly three quarters (74.4%) of sectoral value added and employed more than half (53.5%) of the workforce in 2009, as well as having three fifths (60.1%) of the enterprise population. The second largest subsector was real estate activities on a fee or contract basis (Group 68.3) which contributed almost one fifth (19.5%) of value added and twice this share (39.3%) of the sector's workforce. The smallest subsector was buying and selling of own real estate (Group 68.1) with a 6.9% share of the sectoral workforce.

The high wage-adjusted labour productivity ratio recorded for the EU-27's real estate activities sector in 2009 was pulled up by the high ratios recorded for renting and operating of own or leased real estate (397.2%) and buying and selling of own real estate (300% in 2008), while the ratio recorded for real estate activities on a fee or contract basis (132.3%) was just below the non-financial business economy average (138.8%). In contrast, all three subsectors recorded gross operating rates well above the non-financial business economy average (9.7% in 2009): buying and selling of own real estate and real estate activities on a fee or contract basis both recorded rates of 20.0% (in 2008 and 2009 respectively), while renting and operating of real estate recorded a rate of 48.8% which was the second highest gross operating rate of all non-financial business economy activities at the NACE group level lower only than for transport via pipelines (Group 49.5).

Country analysis

Germany had by far the highest value added for real estate activities in 2009 among the EU Member States, generating 27.6% of the EU-27 total, which was slightly less than the combined shares of France (15.4%) and the United Kingdom (13.5%), and well above Germany's share of EU-27 value added within the non-financial business economy as a whole (22.1%). Nevertheless, there were six Member States that were more specialised in this sector (in value added terms). This was particularly true for Sweden and Latvia, as real estate activities accounted for 8.1% and 6.6% respectively of their non-financial business economy value added in 2009; the other four countries with a higher specialisation in real estate activities than in Germany were the Netherlands, Estonia, Austria and Finland. In value added terms the least specialised Member States were Ireland and Cyprus where real estate activities accounted for 1.0% and 1.1% respectively of non-financial business economy value added.

Italy had the greatest value added in the buying and selling of own real estate sector in 2009 (EUR 4100 million), while Germany had the highest level of value added for the renting and operating of own or leased real estate subsector (EUR 48500 million or 30.2% of the EU-27 total), while the United Kingdom was the leading player in the real estate activities on a fee or contract basis subsector (EUR 10600 million or 25.1% of the EU-27 total). While these large Member States accounted for the largest shares of activity, the highest degrees of specialisation were recorded elsewhere. For the buying and selling of own real estate subsector Portugal and Hungary were the most specialised countries and the only Member States where this subsector accounted for 1% or more of non-financial business economy value added. Sweden, Latvia, Luxembourg and Austria were the most specialised Member States for the renting and operating of own or leased real estate subsector with this subsector generating at least 4% of non-financial business economy value added, a share that rose as high as

7.4% in the case of Sweden. The most specialised Member States for real estate activities on a fee or contract basis, were Latvia, Poland, the United Kingdom and Poland, as these were the only Member States to report that this subsector contributed at least 1% of non-financial business economy value added; the highest share was recorded in Latvia (2.5%).

Wage-adjusted labour productivity ratios for the real estate activities sector were generally very high in nearly all Member States, with only Ireland (99.9%), Italy (170.6%) and Spain (194.2%) recording ratios below the threshold of 200% (which indicates that apparent labour productivity was at least twice as high as average personnel costs). By far the highest wage-adjusted labour productivity ratios for real estate activities were recorded in Romania (556.8%), Finland (542.8%) and Austria (451.1%).

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

The services of real estate activities are very diverse: real estate agents let (rent) or sell on a commission basis; traders buy and sell property; valuers, facilities and estate managers provide professional services; and finally owners let property. Most of these activities are related to the secondary market concerned with existing property, although some, such as property developers for own operation are active in the primary market and are therefore closely related to the construction sector.

This wide range of real estate activities have very different cost structures and revenue streams. As such, care has to be taken when comparing them, particularly when trying to measure the size of each subsector or their use of capital or labour. In particular, when enterprises are the owner of a good that they rent or lease, their financial costs and depreciation charges may constitute the main element of their total costs, but these are not considered when calculating gross value added or indicators of productivity based on this.

As regards the policy context of the real estate activities, this sector crosses a number of important areas, including – among others – the internal market, consumer protection, the energy performance of buildings and taxation.

The [Services Directive](#) seeks to remove legal and administrative barriers to trade. From the perspective of property professionals the principles of the freedom of establishment and free movement of services permit real estate agents and other professionals to offer their services outside their country of origin. From a consumer perspective the opening up of the internal market has been achieved while at the same time ensuring that sufficient safeguards are in place to protect consumers (for example, timeshare arrangements or alternative dispute resolution, which makes it easier for consumers to have complaints and problems dealt with without going to court).

Real estate statistics - NACE Rev. 1.1

Data from January 2009. Most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev. 1.1](#)), the present article covers real estate statistics, corresponding to NACE Division 70, which is part of the [real estate, renting and leasing](#) sector.

Real estate services are classified alongside a range of business services within NACE Section K. However, some parts of the activity have a close relationship with the construction sector (see [Construction statistics - NACE Rev. 1.1](#)) and others with architectural activities (see [Architectural, engineering and technical services statistics - NACE Rev. 1.1](#)).

Table 2: Real estate activities (NACE Division 70). Main indicators, 2006 (1)

One indicator of the level of activity in the residential property market is lending for house purchases. Data from the [European Central Bank \(ECB\)](#) indicate how the stock of such lending, was increasing at a progressively stronger rate throughout the period 2003 to 2005, and peaked at 12.1% in March and April 2006; since when the rate of growth slowed mirroring the increase in interest rates that started in December 2005.

Structural profile

There were around 1.1 million [enterprises](#) active in the [EU-27](#) 's real estate services sector (NACE Division 70) in 2006 and together they [employed](#) 2.9 million persons. These enterprises generated EUR 570 billion of [turnover](#) , from which close to half (EUR 270 billion) was retained as [value added](#) . As such, this sector's contribution to the total for real estate, renting and leasing (NACE Divisions 70 and 71) ranged in 2005 and 2006 between three quarters for turnover to four fifths for value added and employment.

Germany had by far the largest real estate services sector in the EU-27, generating EUR 64.4 billion of value added, close to one quarter of the EU-27 total. In contrast the United Kingdom had the largest workforce in this sector, with just over half a million persons employed in real estate services, some 17.5% of the EU-27 total. As a proportion of value added in the non-financial business economy (NACE Sections C to I and K), the real estate services sector in 2006 was largest¹⁰⁷ in Denmark, generating 12.2% of the [non-financial business economy](#) value added, far ahead of the proportions recorded in Latvia and Sweden (just over 7%). This sector's smallest contribution to non-financial business economy value added was in Greece where it was less than 1%.

Expenditure and productivity

In 2006, gross [tangible investment](#) in the real estate services sector was valued at EUR 177 billion, equivalent to 70.2% of such investment in real estate, renting and leasing. The [investment rate](#) in the real estate services sector was 65.6%, slightly below the real estate, renting and leasing average of 74.1%, but still more than three and a half times as high as the non-financial business economy average, and the third highest investment rate among the non-financial business economy NACE divisions in 2005 or 2006. In more than one third of the Member States the investment rate in this sector was above 100%, indicating that investment exceeded value added: particularly high investment rates were recorded in Bulgaria and Greece.

¹⁰⁷Bulgaria, Cyprus, Poland and Romania, 2005; Luxembourg, Malta and the Netherlands, not available.

Another indicator of the capital intensive nature of this sector in the EU-27, though less spectacular than the investment rate, is the relatively low (13.3%) share of [personnel costs](#) in operating expenditure in 2006, below the non-financial business economy average (16.1%). Average personnel cost in 2006 in the EU-27's real estate services sector were EUR 29.9 thousand per employee, very close to the non-financial business economy average.

As noted in the [overview article](#) , financial costs and depreciation charges may constitute the main costs faced in some parts of the real estate sector, and these are not considered when calculating [gross value added](#) . As such, [productivity](#) measures based on gross value added tend to be particularly high. Apparent [labour productivity](#) was EUR 93.1 thousand per person employed for real estate services in the EU-27 in 2006, more than double the non-financial business economy average. The combination of high apparent labour productivity yet typical average personnel costs resulted also in a very high [wage-adjusted labour productivity ratio](#) of 311.9%, which was also more than double the non-financial business economy average (151.1%). In every Member State the wage-adjusted labour productivity ratio in real estate services exceeded 200%, and was always above the national non-financial business economy average.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include the European Central Bank.

Context

Real estate services and renting and leasing services are provided to households and to business clients. The use of renting or operating leasing can increase financial flexibility, reducing the need to commit own capital, whether for buildings, machinery, equipment or appliances.

The activities of real estate services are very diverse: real estate agents let (rent) or sell on a commission basis; traders buy and sell property; valuers, facilities and estate managers provide professional services; and finally owners let property. Most of these activities are related to the secondary market concerned with existing property, although some, such as property developers are active in the primary market and are therefore more closely related to construction. The wide range of real estate service activities have very different cost structures and revenue streams and care has to be taken when comparing them, particularly when trying to measure the size of each subsector or their labour productivity. In particular, when enterprises are the owner of a good that they rent or lease, their financial costs and depreciation charges may constitute the main element of their total costs, but these are not considered when calculating gross value added or indicators of productivity based on this.

Table 6: Renting of machinery and equipment without operator and of personal and household goods (NACE Division 71). Main indicators, 2006 (1)

Main statistical findings

Structural profile

The number of persons employed by the 1.3 million enterprises active in the EU-27's real estate, renting and leasing sector (NACE Divisions 70 and 71) was EUR 3.3 million in 2005. Within this total, paid employees made up 72.9% of the workforce, some 13.4 percentage points below the non-financial business economy average (NACE Sections C to I and K). Both subsectors recorded a low share of paid employees (and therefore a high share of working proprietors and unpaid family workers), particularly real estate where the share of paid employees was 69.3% in 2006, more than 10 percentage points lower than the next lowest share (retail trade

and repair) across all of the non-financial business economy NACE divisions in 2005 or 2006. This workforce generated EUR 340 billion of **value added** in 2006, 6.0% of the non-financial business economy's total, more than double this sector's 2.6% (in 2005) share of employment. These remarkable differences result from the capital intensive nature of this sector. In the renting and leasing subsector as well as parts of the real estate subsector (notably letting of own property), enterprises own a good, often of high value, and this good is then rented or leased out to customers. As such, financial costs and depreciation charges may constitute the main element of total costs, neither of which are considered when calculating **gross value added**.

Real estate (NACE Division 70) accounted for close to four fifths (79.4%) of the sector's value added in 2006 and a slightly larger share of employment (81.8%) in 2005. Renting and leasing (NACE Division 71) naturally made up the remainder of the sector, and generated close to one quarter (23.1%) of the sector's EUR 650 billion of **turnover** in 2005.

Germany, with EUR 82.1 billion of value added, accounted for the largest share (24.1%) of the EU-27's real estate, renting and leasing sector in 2006. The United Kingdom had the second largest share (18.6%) of EU-27 value added in this sector but the largest workforce, 686.3 thousand persons, equivalent to 20.5% of the EU-27 total in 2005. In terms of its contribution to value added in the non-financial business economy, the real estate, renting and leasing sector represented 12.9% of the total in Denmark, more than double the EU-27 average and far ahead of the next highest share. In fact Danish specialisation in this sector was so great that this sector was the second largest sector in the Danish non-financial business economy (based on the structural business statistics in Statistics Explained). At the other end of the spectrum, these activities accounted for less than 2% of non-financial business economy value added in Greece, Slovenia and Bulgaria. In all Member States real estate, renting and leasing accounted for a smaller proportion of non-financial business economy employment than value added.

The regional specialisation of the real estate, renting and leasing sector is shown in the map which is based on the non-financial business economy employment share of this sector. The most specialised regions (at the level of detail shown in the map) were Latvia (considered as one region) and the Algarve (Portugal), followed by inner London (the United Kingdom). Many of the regions least specialised in this sector were Greek, including 10 of the 11 least specialised: these, along with one Romanian region, all recorded 0.5% or less of their non-financial business economy employment in this sector.

An analysis of the EU-27's real estate, renting and leasing sector in 2005 shows that more than one half (52.4%) of value added was generated by **micro enterprises**, namely those with less than 10 persons employed, nearly two and a half times the average share within the non-financial business economy. **Large enterprises** (with 250 or more persons employed) contributed a particularly low share of value added in this sector. Both subsectors recorded a dominant role for micro enterprises: for real estate the value added share of micro enterprises was 57.1% in 2006 while for renting and leasing the share was 35.9% in 2005, the highest and third highest shares among all of the non-financial business economy NACE divisions in 2005 or 2006.

Employment characteristics

The characteristics of the real estate, renting and leasing sector's workforce in the EU-27 were fairly typical of service sectors, in that the shares of male workers and full-time workers were below the non-financial business economy average. Nevertheless, a more complex picture is revealed when analysing the two subsectors that make up the sector. In 2007, according to the **Labour force survey**, 53.0% of the persons employed in the sector as a whole were male, some 11.9 percentage points lower than the non-financial business economy average. The proportion of male workers within the renting and leasing subsector was higher, at 67.9%. In the real estate subsector the male and female shares were almost identical, with the share of male workers below 40% in Luxembourg, Bulgaria and Slovenia.

In the EU-27 as a whole, full-time employment was notably less common in real estate activities (78.6%) than in renting and leasing (83.9%), but this was not the case in all Member States, most notably in Slovenia and Ireland where the incidence of full-time employment was at least 5 percentage points higher in real estate than in renting and leasing.

In terms of age profile, there was a much higher proportion of the EU-27's real estate, renting and leasing workforce that were aged 50 or over (29.8%) than the average for the non-financial business economy (21.9%). This difference reflects, to a large degree, the fact that just under one third (32.2%) of workers in real estate

services were aged 50 or more in 2007. In contrast, in the renting and leasing subsector the proportion of the workforce aged 50 or over was just 18.7%, and as such below the non-financial business economy average.

Expenditure, productivity and profitability

The two subsectors within the real estate, renting and leasing sector were both relatively capital intensive services, but to quite different degrees. In 2006 gross [tangible investment](#) in the EU-27's real estate, renting and leasing sector was valued at EUR 252 billion, equivalent to 74.1% of the sector's value added. The real estate subsector recorded a lower [investment rate](#), 65.6%, that was nevertheless more than three and a half times as high as the average rate for the non-financial business economy. The level of investment in the leasing and renting subsector exceeded value added, resulting in an investment rate of 107.1%. At the NACE division level these were the highest and third highest investment rates recorded within the EU-27's non-financial business economy in 2005 or 2006.

An analysis of expenditure in 2006 shows that [personnel costs](#) accounted for 13.3% of [operating expenditure](#) in the EU-27's real estate subsector, and 16.7% in the renting and leasing subsector, the latter marginally higher than the non-financial business economy average (16.1%). Average personnel costs were also slightly higher for the renting and leasing subsector than for real estate, but in both cases quite close to the non-financial business economy average. In contrast, the apparent [labour productivity](#) ratio was notably greater for renting and leasing than it was for real estate, but in both subsectors this ratio was well above the non-financial business economy average. For the EU-27's renting and leasing subsector this ratio indicated that on average each person employed generated EUR 125.0 thousand of added value in 2005, the fifth highest level for this ratio among the non-financial business economy NACE divisions in 2005 or 2006, and close to three times the non-financial business economy average (EUR 42.3 thousand) in 2005. As noted above, care has to be taken with the ratios based on value added for the renting and leasing subsector, and parts of the real estate subsector: financial costs and depreciation charges may constitute the main costs for these activities and these are not considered when calculating [gross value added](#) and the [gross operating surplus](#).

The combination of particularly high apparent labour productivity and slightly higher than average personnel costs led to [wage-adjusted labour productivity ratios](#) of 400% in 2005 for the EU-27's renting and leasing subsector, and 311.9% for the real estate subsector in 2006, both more than double the non-financial business economy average. These two subsectors recorded the third and sixth highest wage adjusted labour productivity ratios among the non-financial business economy NACE divisions in 2005 or 2006. Every Member State¹⁰⁸ recorded a higher wage-adjusted labour productivity ratio for the real estate, renting and leasing sector than for the non-financial business economy, with Cyprus (2005), Denmark and Austria recording ratios in this sector at least three times as high as their national non-financial business economy average ratios.

The gross operating rate shows the percentage relationship between the gross operating surplus (value added minus personnel costs) and turnover, and is a measure of operating [profitability](#). The gross operating rate of the EU-27's real estate, renting and leasing sector was 39.2% in 2005, close to four times as high as the non-financial business economy average of 10.0% in the same year. This rate was high for both subsectors, the second and third highest levels for this rate among the non-financial business economy NACE divisions in 2005 or 2006.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include the Labour force survey (LFS).

¹⁰⁸Bulgaria, Cyprus, Poland and Romania, 2005; Ireland, Luxembourg, Malta, the Netherlands and Sweden, not available.

Context

Real estate services and renting and leasing services are provided to households and to business clients. The use of renting or operating leasing can increase financial flexibility, reducing the need to commit own capital, whether for buildings, machinery, equipment or appliances.

Recruitment and personnel selection services statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database .

This article presents the [European Union structural business statistics](#) for NACE Group 74.5, which includes personnel search, selection referral, head-hunting and job placement services. Personnel services may be supplied to persons looking for work or to an [enterprise](#) trying to hire. The data presented also cover labour-contracting activities (for example, temporary work agencies); however, they do not comprise farm labouring or the performing arts.

Table 2: Labour recruitment services (NACE Group 74.5), 2005

Personnel services have grown mainly as a consequence of the [outsourcing](#) trend, using the flexibility and expertise provided by enterprises in this sector (for example, knowledge of the [labour market](#) and selection procedures) instead of trying to employ personnel directly.

On 27 June 2007, the [European Commission](#) proposed in a Communication the establishment of eight common principles of flexicurity, a policy approach that gains growing importance as an instrument that combines labour market flexibility with employment security and the need to respect workers rights and working conditions. This policy is a response to the challenges posed by globalization, with the aim of making EU labour markets more flexible while providing employment security at the same time. In this framework, enterprises acting in personnel services are directly concerned.

Structural profile

The EU's personnel services sector (NACE Group 74.5) generated EUR 96.2 billion of [value added](#) in 2006 from EUR 127.9 billion of [turnover](#), equivalent to 10.8% of the wealth that was created in the [business services](#) sector (NACE Divisions 72 and 74) and 7.3% of the turnover. In turnover terms this was the smallest of the

business services activities, and it was the second smallest in value added terms. However it was with respect to employment that the 71.1 thousand enterprises in the personnel services sector made their greatest contribution: the personnel services workforce consisted of 3.8 million persons, equivalent to 17.1% of the business services total, making it the third largest workforce within business services. The significant differences in the contribution of personnel services to the business services total depending on the indicator studied can be largely explained by the nature of a much of this sector, namely, to employ people to undertake work for clients in other sectors.

Among the Member States, close to one third of the EU's value added came from the United Kingdom (32.1%), the largest market for personnel services, as well as the largest employer. France and Germany were respectively the second and third largest contributors, both in terms of value added or employment. These three Member States dominated this sector, collectively accounting for 69.7% of EU value added; for comparison, their share within business services was 61.2% and within the non-financial business economy as a whole it was 53.5%. The Netherlands was the fourth largest Member State in personnel services, ahead of both Italy and Spain. In particular, the size of the Dutch workforce was remarkable, with over half a million persons employed in personnel services. In value added terms the United Kingdom and France were the most specialised in this sector, both registering 2.9% of their non-financial business economy (NACE Sections C to I and K) value added in this sector. Cyprus, Bulgaria (both 2005), Greece, Latvia and Lithuania were the least specialised in this sector, all generating 0.2% or less of their non-financial business economy value added in personnel services.

Product analysis and type of personnel

A breakdown of turnover by product for the personnel services sector shows that in 2005 supply services of personnel generated the largest share of turnover in most of the Member States for which data are available, as compared with placement services. Only in Latvia and Lithuania did the placement services of personnel (such as executive search services) generate more than half of the total sales. It should be borne in mind that turnover for placement services tends to correspond to a fee for the placement, whereas the turnover for the supply of personnel involves both a fee for arranging the supply as well as the payments made to the personnel supplied.

Expenditure and productivity

In several respects concerning expenditure and productivity the EU's personnel services sector is atypical for business services. This sector recorded by far the lowest investment rate, just 1.2% in 2006, from investments valued at EUR 1.2 billion. This was not only the lowest rate within business services, but it was also the lowest investment rate of all NACE groups within the non-financial business economy in 2005 or 2006. In contrast, expenditure on personnel costs was high, as these costs accounted for 72.6% of all operating expenditure in this sector; this was 1.8 times as high as the average share in business services and 4.5 times as high as the average share for the non-financial business economy, and unsurprisingly was the highest share for all NACE groups within the non-financial business economy in 2005 or 2006.

Apparent labour productivity and average personnel costs were both lower in the EU's personnel services sector than respective averages for business services in 2006. Indeed, apparent labour productivity was EUR 25.4 thousand per person employed for personnel services (EUR 40.2 thousand for the business services) and average personnel costs were EUR 21.6 thousand per employee (EUR 31.1 thousand for business services), and in both cases these were the second lowest levels among the business services sectors. It should be noted that these ratios are to some extent influenced by the high incidence of part-time and temporary work in the personnel services sector, as both of these measures are based on simple head counts of persons employed or employees. These characteristics of the personnel services' workforce do not affect the wage adjusted labour productivity ratio as much, but nevertheless this ratio was just 117.5% for personnel services in 2006, the lowest ratio among all of the business services sectors.

Data sources and availability

The main part of the analysis in this article is derived from structural business statistics (SBS), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other possible data sources include [short-term statistics](#) and the [Labour force survey](#) . In addition, use has also been made of specialist sources for particular areas, notably [transport](#), [energy](#), [research and development](#), [environment](#), [tourism](#) and [information society statistics](#).

Context

The freedom to provide services and the freedom of establishment are central principles to the [internal market](#) for services and are set out in the [EC Treaty](#) . They guarantee EU enterprises the freedom to establish themselves in other Member States, and the freedom to provide services on the territory of another EU Member State. The [Directive on services in the internal market](#) aims to achieve a genuine internal market in services, removing legal and administrative barriers to the development of services activities between Member States. The Directive was to be implemented by Member States by the end of 2009 at the latest. As well as covering most [business services](#) (with the notable exception of services of temporary work agencies), the Directive applies to a wide variety of services including industrial and construction activities, as well as distributive trades, hotels and restaurants, travel agents, real estate and renting services.

Table 5: Recycling (NACE Division 37). Main indicators, 2006 (1)

NACE characterises recycling as the processing of used or unused, sorted or unsorted, waste and scrap into secondary raw materials which can then be used by other sectors as an intermediate good. Recycling, under this

definition, involves a number of treatment stages, such as sorting, crushing, mechanical reduction, stripping, separation and cleaning which may be followed by further treatments to prepare raw materials for use by other sectors.

Recycling does not extend to the production of new final products, nor does it include the re-use of products (when no real transformation process is required). Nor does this article cover waste management, which NACE classifies separately, although it and recycling are closely related activities. Note also that substantial recycling may also be carried out by [enterprises](#) as ancillary activities, without the involvement of enterprises in the recycling sector.

Main statistical findings

An analysis of the volume of the recovery (reclamation, regeneration, recycling, re-refining) of waste shows that in excess of 1088 billion tonnes of waste were recovered in the EU in 2006, with metallic waste, which is an important source of materials for metal processing activities, accounting for around 6.3% of this total.

Structural profile

In 2006, the [EU-27](#) 's recycling sector (NACE Division 37) had around 15.7 thousand enterprises which generated a value added of EUR 8.1 billion and employed 150.5 thousand persons. The recycling sector therefore contributed around one quarter of the total [value added](#) (25.8%) for water supply and recycling (NACE Divisions 41 and 37) and closer to three tenths (28.9%) of its workforce. In 2006 recycling was the smallest manufacturing (NACE Section D) NACE division in the EU-27 in [employment](#) and value added terms. In 2005 the EU-27

's recycling sector was fairly equally split between the metal recycling subsector (NACE Group 37.1) and non-metal recycling (NACE Group 37.2). The non-metal recycling subsector was comparable in employment terms with the metal recycling subsector, both with a workforce of about 71.0 thousand persons. In value added terms, metal recycling was slightly larger than non-metal recycling in 2005, but incomplete data already available for 2006 shows that value added in both of these subsectors increased significantly in 2006.

France and the United Kingdom had the largest recycling sectors in the EU-27 in 2006, both in terms of value added and employment. Romania (2005) and Slovenia had the highest value added specialisation among the Member States¹⁰⁹ in recycling, as this sector contributed 0.3% or more of their [non-financial business economy](#) (NACE Sections C to I and K) value added. In most of the Member States the metal recycling subsector generated higher value added than the non-metal recycling subsector, with the reverse situation only in two of the larger Member States, Germany and Italy, as well as in Belgium and the Netherlands (2005).

Expenditure and productivity

The EU-27's recycling sector recorded [tangible investment](#) valued at EUR 2.1 billion in 2006, leading to an [investment rate](#) of 25.9%, well above the non-financial business economy average of 18.4%. Denmark, Italy and the Czech Republic all recorded investment rates in this sector that were at least twice as high as the average for their national non-financial business economies.

[Personnel costs](#) accounted for a relatively low proportion of [operating expenditure](#) in the EU-27's recycling sector, just 9.6%, which was well below the non-financial business economy average of 16.1%. This share was particularly low for the metal recycling subsector (6.7%), perhaps reflecting the relatively high expenditure on the purchase of metal waste and scrap for processing, whereas for non-metal recycling the share of personnel costs (16.7%) was just above the non-financial business economy average. Average personnel costs in 2006 were EUR 27.3 thousand per employee in the EU-27's recycling sector, while apparent [labour productivity](#) was EUR 53.9 thousand per person employed. This resulted in a [wage-adjusted labour productivity ratio](#) of 197.6% in 2006, well above the non-financial business economy average (151.1%). In 2006, the vast majority of Member States recorded a higher wage-adjusted labour productivity ratio in the recycling sector than in the non-financial

¹⁰⁹Bulgaria, Cyprus, Poland and Romania, 2005; Ireland, Greece, Malta and the Netherlands, not available.

business economy as a whole, the exceptions being Denmark, Estonia, Lithuania and Poland (2005). The highest¹¹⁰ wage-adjusted labour productivity ratio in the recycling sector was recorded in Bulgaria where it reached an exceptional 1180.7%, whereas Denmark was the only Member State to record a wage-adjusted labour productivity ratio in the recycling sector that was below 100%.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include the Eurostat waste statistics.

Context

In November 2008 a new Directive of the [European Parliament](#) and the [Council](#) on waste ([Directive 2008/98](#)) of the European Parliament and of the Council of 19 November 2008 on waste.</ref> was adopted, replacing the 30 year old existing waste Directive as well as Directives on hazardous waste and waste oils. The new Directive sets recycling targets to be achieved by 2020, establishes a clear hierarchy of waste management options, and clarifies a number of important definitions, such as recycling, recovery and waste itself.

Main statistical findings

Structural profile

The remediation and other waste management services sector (Division39) included 2133 enterprises in the EU-27 in 2009. This sector employed 38200 persons and recorded EUR1637 million of value added in 2009. As such, it was the smallest sector (for which data are available) within the EU-27's non-financial business economy (Sections B to J and L to N and Division 95) at the NACE division level, contributing a 0.03% share to both total employment and value added. Within water supply, sewerage, waste management and remediation activities (Section E) the remediation and other waste management services sector contributed 3.0% of employment and 2.1% of value added.

The apparent labour productivity of the EU-27's remediation and other waste management services sector in 2009 was EUR43 thousand per person employed, just above the non-financial business economy average of EUR41.6 thousand per person employed but considerably below the water supply, sewerage, waste management and remediation activities average of EUR62 thousand per person employed. Nevertheless, average personnel costs per employee in the remediation and other waste management services sector were EUR33.0 thousand, slightly higher than the averages for the non-financial business economy (EUR30.0 thousand) and water supply, sewerage, waste management and remediation activities (EUR31.5 thousand). The wage-adjusted labour productivity ratio combines the two previous indicators and shows the extent to which value added per person employed covers average personnel costs per employee. The EU-27's remediation and other waste management services sector had a wage-adjusted labour productivity ratio of 136.8% in 2009. Due to the slightly high average personnel costs this was just below the non-financial business economy average (138.8%) and due to the relatively low apparent labour productivity this was well below the water supply, sewerage, waste management and remediation activities average (196.8%).

The gross operating rate (the relation between the gross operating surplus and turnover) is a measure of operating profitability. In 2009 this rate was 11.0% for the EU-27's remediation and other waste management services sector, slightly above the non-financial business economy average (9.7%) but considerably lower than the water supply, sewerage, waste management and remediation activities average (20.9%).

Country analysis

The largest Member State in the remediation and other waste management services sector in 2009 was Spain, with a workforce of 18904 and value added of EUR758.5 million, equivalent to 49.5% of the EU-27 workforce and 46.3% of EU-27 value added. The Spanish share of EU-27 value added recorded in this sector was the highest share for Spain in any of the non-financial business economy NACE divisions (with data available) in 2009. Italy was the only other Member State to have a share of the EU-27 workforce in excess of 10%, while France and Italy both contributed more than 10% of EU-27 value added; note that German value added data is not available.

Unsurprisingly, Spain was by far the most specialised Member State in the remediation and other waste management services sector in 2009. This sector contributed 0.16% of Spanish non-financial business economy value added, more than double the next highest share which was 0.07% in Hungary.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the remediation and other waste management services sector in the EU, as covered by NACE Rev.2 Division39. This division includes the provision of remediation services, in other words, the clean-up of contaminated buildings and sites, soil, surface or ground water, oceans, seas and coastal areas. Mechanical, chemical and biological methods are included, either in situ or ex situ. Also included are activities such as the decontamination of industrial and power plants, cleaning-up following accidental pollution, asbestos, lead paint, and other toxic material abatement and specialised pollution-control activities.

This division contains one group and one class only and so there is no analysis of subsectors in this article.

Outdoor sweeping, watering of streets and similar activities are excluded from the information presented in this article as these are classified as [services to buildings and landscape activities](#) (Division81).

Table 4b: Key indicators, rental and leasing activities (NACE Division 77), 2009 - Source: Eurostat (sbs_na_1a_se_r2)

Main statistical findings

Structural profile

There were 158 thousand enterprises operating with rental and leasing activities (Division 77) as their principal activity in the EU-27 in 2009. Together they employed 640 thousand persons, equivalent to 0.5% of the non-financial business economy (Sections B to J and L to N and Division 95) workforce or 5.3% of those employed in administrative and support services (Section N).

The rental and leasing activities sector generated EUR 71 985 million of value added, which was a considerably higher share of both the non-financial business economy total (1.3%) and of the administrative and support services total (20.6%) than the shares recorded for employment. These differences can, in part, be explained by the specific character of rental and leasing activities, such as their capital-intensive nature. Indeed, these activities have very different cost structures and revenue streams and care should be taken when making comparisons with other sectors and subsectors in the non-financial business economy. Enterprises that engage in rental and leasing activities own the goods that they rent or lease, with financial costs and depreciation charges often constituting the main element of their total costs: these costs and charges are not considered when calculating gross value added and so productivity and profitability measures based on value added are often very high. One example of this phenomena is **apparent labour productivity**, which for the EU-27's rental and leasing activities sector reached EUR 112 thousand per person employed in 2009, considerably above the non-financial business economy average of EUR 41.6 thousand per person employed and almost four times as high as the administrative and support services average of EUR 29 thousand per person employed. While the rental and leasing activities sector had the ninth highest level of apparent labour productivity among the NACE divisions that make-up the non-financial business economy, **average personnel costs** were not particularly high, averaging EUR 31.6 thousand per employee across the EU-27 in 2009, compared with EUR 30.0 thousand per employee for the whole of the non-financial business economy and an average of EUR 20.9 thousand per employee for administrative and support services. These considerable differences resulted in the **wage-adjusted labour productivity ratio** – which combines the two previous indicators and shows the extent to which value added per person employed covers average personnel costs per employee – attaining 355.6% for the EU-27's rental and leasing activities sector in 2009. This was the second highest ratio among any of the NACE divisions that constitute the non-financial business economy, and stood more than 2.5 times as high as the non-financial business economy average (138.8%) or the administrative and support services average (139.1%).

In a similar vein, the **gross operating rate** (which presents the relation between the **gross operating surplus** and **turnover**) and is one measure of operating profitability – stood at 37.6% for the EU-27's rental and leasing activities sector in 2009, almost four times as high as the non-financial business economy average (9.7%) and

almost 2.5 times as high as the administrative and support services average (15.2%). This was the third highest level of operating profitability (using this measure) among the NACE divisions within the non-financial business economy – ranking just behind [real estate activities](#) (Division68) and [sewerage](#) (Division37)].

Sectoral analysis

Just over half (51.9%) of the enterprises within the EU-27's rental and leasing activities sector in 2009 were classified as part of the renting and leasing of other machinery, equipment and tangible goods subsector (Group77.3). Two subsectors accounted for the majority of the remaining enterprises, with the renting and leasing of personal and household goods (Group77.2) taking a 25.7% share, while the renting and leasing of motor vehicles (Group77.1) accounted for 20.0%, leaving just 2.3% of the sectoral total for enterprises whose main activity was the leasing of intellectual property and similar products, except copyrighted works (Group77.4, hereafter referred to as the leasing of intellectual property).

The relative shares of sectoral employment between the four groups that make-up the rental and leasing activities sector were broadly similar to those recorded for the breakdown of the number of enterprises: the renting and leasing of other machinery, equipment and tangible goods subsector had the highest share (49.6%), followed by the renting and leasing of motor vehicles (25.0%), the renting and leasing of personal and household goods (22.6%) and the leasing of intellectual property (2.0%).

However, the nature of the goods being rented or leased had a influence on the sectoral breakdown of value added, which was considerably higher for the renting and leasing of motor vehicles. The renting and leasing of other machinery, equipment and tangible goods subsector remained the largest subsector, by this measure, with a 48.5% share of sectoral value added, followed by the renting and leasing of motor vehicles (39.3%), while the relative importance of the renting and leasing of personal and household goods was much lower (7.3%).

These differences in value added were reflected in the wide range of EU-27 apparent labour productivity ratios, with highs of EUR200 thousand per person employed for the leasing of intellectual property in 2008 and EUR170 thousand per person employed for the renting and leasing of motor vehicles in 2009, respectively the sixth and seventh highest values among the NACE groups within the non-financial business economy. Apparent labour productivity for the renting and leasing of other machinery, equipment and tangible goods was also relatively high (EUR110 thousand per person employed in 2009), in contrast to the renting and leasing of personal and household goods, where apparent labour productivity – at EUR36 thousand per person employed – was below the non-financial business economy average (EUR41.6 thousand per person employed).

There were relatively high average personnel costs (EUR60.0 thousand per employee in 2008) for the EU-27's leasing of intellectual property. Otherwise, personnel costs per employee within the rental and leasing activities sector ranged from EUR34.6 thousand per employee for the renting and leasing of other machinery, equipment and tangible goods through EUR30.0 thousand per employee for the renting and leasing of motor vehicles (the same level as the average for the whole of the non-financial business economy) down to EUR24.3 thousand per employee for the renting and leasing of personal and household goods.

The EU-27 wage-adjusted labour productivity ratio was above the non-financial business economy average for all four subsectors that make-up the rental and leasing activities sector in 2009. Although relatively close to the non-financial business economy average (138.8%) for the renting and leasing of personal and household goods subsector (148.8%), this ratio rose to 317.5% for the renting and leasing of other machinery, equipment and tangible goods, to 352.3% for the leasing of intellectual property (in 2008), and peaked at 573.2% for the renting and leasing of motor vehicles; the latter was the fourth highest ratio among any of the NACE groups within the non-financial business economy.

For the gross operating rate, data is only available for three of the NACE groups that form the rental and leasing activities sector. This measure of operating profitability was well above the EU-27 non-financial business economy average of 9.7% in 2009 for all three subsectors, ranging from 20.1% for the renting and leasing of personal and household goods, through 38.0% for the renting and leasing of other machinery, equipment and tangible goods to peak at 40.2% for the renting and leasing of motor vehicles – the fifth highest ratio among the NACE groups within the non-financial business economy.

Country analysis

Germany recorded the highest share (23.3%) of EU-27 value added within the rental and leasing activities sector in 2009. France (19.0%) and the United Kingdom (17.8%) were also relatively important producers in value added terms; none of the remaining Member States had a double-digit share of the total, with the next highest share being recorded for Spain (7.9%). The 1.2% share of EU-27 value added recorded in this sector for Luxembourg was the highest share for Luxembourg in any of the non-financial business economy NACE divisions (with data available) in 2009. In terms of persons employed, the United Kingdom had the largest workforce for rental and leasing activities, at 148.5 thousand persons in 2009, equivalent to 23.2% of the EU-27 workforce, followed by Germany (15.6%), France (12.6%, note that the data refer to employees and not persons employed) and Spain (12.2%).

A breakdown of activity at a more detailed level shows that France recorded the highest share of EU-27 value added for the renting and leasing of personal and household goods (28.6%) and the renting and leasing of motor vehicles (19.1%), while the highest share of EU-27 value added for the renting and leasing of other machinery, equipment and tangible goods was recorded in Germany (27.7%).

In value added terms, Luxembourg was by far the most specialised Member State in the rental and leasing activities sector in 2009, as 5.8% of its non-financial business economy value added was generated in this activity; this figure was influenced by a very high share of value added within the leasing of intellectual property subsector. Austria (2.1% of non-financial business economy value added) and the two remaining Benelux countries of Belgium and the Netherlands (both 1.7%) were also relatively specialised in the rental and leasing activities sector in 2009.

With the exception of Denmark (where there was negative value added), all of the Member States for which data are available reported wage-adjusted labour productivity ratios for rental and leasing activities in 2009 that were higher than their non-financial business economy averages. This was particularly the case for Germany, Hungary and Romania, where the wage-adjusted labour productivity ratio for rental and leasing activities was more than three times as high as the average, rising to almost 4.8 times as high as the average in Austria. In fact, in Belgium, Germany, Luxembourg, Austria and Romania the wage-adjusted labour productivity ratio in this sector was the highest in 2009 among all of the NACE divisions within the non-financial business economy.

A similar pattern was observed for the gross operating rate, which was considerably higher for rental and leasing activities than for the whole of the non-financial business economy, aside from in Denmark (where it was negative). In France, the gross operating rate was 5.7 times as high as the non-financial business economy average, while in Germany, Hungary and Slovakia it stood at least five times as high as the national average. In Bulgaria, Germany, France, Luxembourg, Poland, Portugal, Romania and Slovakia the gross operating rate in this sector was the highest in 2009 among all of the NACE divisions within the non-financial business economy.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the rental and leasing activities sector in the EU, as covered by NACE Rev.2 Division77.

The activities covered within this sector include the renting and leasing of motor vehicles, which involves renting and operational leasing of passenger cars, light vehicles, trucks, heavy motor vehicles and recreational vehicles. The renting and leasing of personal and household goods includes the renting of recreational and sports equipment, video tapes, CDs, DVDs and so on, and all kinds of household or personal goods including jewellery, musical instruments, costumes, household machinery and equipment (for example, tools for home repairs). The renting and leasing of other machinery, equipment and tangible goods (without an operator) includes machinery

and equipment for agricultural, forestry, industrial, construction, transport and office-based activities. Finally, the leasing of intellectual property and similar products (except copyrighted works) includes activities allowing others to use non-financial assets for which a royalty payment or licensing fee is paid to the asset holder. The use of these assets can take various forms, such as permission for reproduction, use in subsequent processes or products, operating businesses under a franchise and so on. The current owners may or may not have created those assets.

This NACE division is composed of four groups:

- renting and leasing of motor vehicles (Group77.1);
- renting and leasing of personal and household goods (Group77.2);
- renting and leasing of other machinery, equipment and tangible goods (Group77.3);
- leasing of intellectual property and similar products, except copyrighted works (Group77.4).

These rental and leasing activities exclude financial leasing (Division64, financial service activities), the renting of [real estate](#) (Division68), as well as the renting of equipment with an operator, for example in [construction](#) (SectionF) or in [transport](#) (SectionH).

Renting and operational leasing statistics - NACE Rev. 1.1

Data from January 2009. Most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers renting and operational leasing statistics, corresponding to NACE Division 71, which is part of the [real estate, renting and leasing](#) sector. The activities covered in this article are:

- renting machinery and equipment without operators;
- renting personal and household goods.

A distinction can be made between operational leasing (or long-term rental) which is included in this article, and financial leasing which is considered as a special form of credit granting and is hence covered as part of the financial and insurance services sector (see [Financial and insurance sector statistics - NACE Rev. 1.1](#)). The renting and leasing of real estate is covered in [Real estate statistics - NACE Rev. 1.1](#).

Table 4: Renting of machinery and equipment without operator and of personal and household goods (NACE Division 71). Main indicators, 2006 (1)

Around 150.2 thousand enterprises were active in the EU-27's renting and leasing sector (NACE Division 71) in 2006, and they generated EUR 70 billion of value added. This sector employed an estimated 600.0 thousand persons in 2005. The renting of transport equipment (NACE Groups 71.1 and 71.2) generated EUR 41.2 billion of value added in the EU-27 in 2005, and accounted for more than half of the renting and leasing sector's value added. The renting of other machinery and equipment (NACE Group 71.3) generated EUR 29.0 billion of value added in 2006, with the renting of personal and household goods (NACE Group 71.4) clearly the smallest subsector with value added of EUR 6.6 billion in 2005. In employment terms, the largest workforce in 2006 was for the renting of other machinery and equipment, where an estimated 280.0 thousand persons were employed: in each of the other two subsectors around 100.0 thousand fewer persons were employed.

The United Kingdom and Germany together generated just over half of the value added in the EU-27's renting and leasing sector in 2006, while France was the only other Member State to record a double digit share. The relative importance in terms of employment was very different, as the United Kingdom had by far the largest workforce, 178.7 thousand persons employed, close to three tenths of the EU-27 total in 2005, more than double the shares recorded in France, Germany and Spain in the same year. Given the very high concentration of the sector's value added in the United Kingdom and Germany, it is unsurprising that these two larger Member States figure among the Member States most specialised in this sector. Austria was however the Member State that was most specialised in the renting and leasing sector¹¹¹, as 1.9% of value added in the Austrian non-financial business economy was generated by this sector in 2006. In these terms, Slovenia and Bulgaria (2005) were the least specialised Member States, as value added from renting and leasing activities contributed just 0.1% and 0.3% respectively of the total value added in their non-financial business economies.

¹¹¹Bulgaria, Cyprus, Poland and Romania, 2005; Malta, the Netherlands and Sweden, not available.

An analysis of the three subsectors¹¹² shows that the renting of transport equipment accounted for 70% or more of the renting and leasing sector's total value added in Luxembourg, Cyprus (2005), Portugal and the Netherlands. In Slovakia, Latvia, Spain and Finland the renting of other machinery and equipment subsector generated more than half of sectoral value added, while only in the small Slovenian renting and leasing sector did the renting of personal and household goods exceed one fifth of total renting and leasing value added.

Expenditure and productivity

Gross **tangible investment** in the EU-27's renting and leasing sector was valued at EUR 75 billion in 2006, some 29.8% of the real estate, renting and leasing total. Most of this investment, EUR 52 billion, was recorded in the renting of transport equipment subsector, with EUR 19 billion for the renting of other equipment, and a relatively low amount in the renting of personal and household goods, just EUR 3 billion. The **investment rate**, which relates the level of investment to the value added, illustrates the very different investment levels of the three subsectors, which in 2005 ranged from 29.8% for the renting of personal and household goods to 130.8% for the renting of transport equipment. As a whole, the EU-27's renting and leasing sector recorded an investment rate of 107.1% in 2006, some 5.8 times as high as the non-financial business economy average, and the highest rate among all of the non-financial business economy NACE divisions in 2005 or 2006.

Unlike for the real estate sector, **personnel costs** represented a relatively normal (16.7%) share of **operating expenditure** in the EU-27's renting and leasing sector in 2006, 0.5 percentage points above the non-financial business economy average. This share was however notably lower (10.0% in 2005) for the renting of transport equipment subsector, while it was above average for the other two subsectors. Average personnel costs ranged from EUR 23100 per employee in the renting of personal and household goods subsector, which was below the non-financial business economy average of EUR 28.8 thousand per employee, to EUR 33.3 thousand per employee in both of the two larger subsectors.

Reflecting the high capital intensity, apparent **labour productivity** for EU-27 renting and leasing activities averaged EUR 125.0 thousand per person employed in 2005. This **productivity** measure rose to EUR 230.4 thousand per person employed for the renting of transport equipment subsector, one of the highest levels recorded in the non-financial business economy. Equally the **wage-adjusted labour productivity ratio** of the renting of transport equipment subsector was very high, 720% in the EU-27 in 2005. This helped boost this ratio for the whole of the EU-27's renting and leasing sector to 400%, the third highest of any NACE division in the non-financial business economy in 2005 or 2006, lower only than two of the mining and quarrying divisions. These high productivity measures in the renting and leasing sector can, in part, be explained by the specific nature of this activity, where the main costs of enterprises are likely to be financial ones covering borrowing as well as depreciation charges, neither of which impact on gross value added.

Data sources and availability

The main part of the analysis in this article is derived from **structural business statistics (SBS)**, including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Context

Real estate services and renting and leasing services are provided to households and to business clients. The use of renting or operating leasing can increase financial flexibility, reducing the need to commit own capital, whether for buildings, machinery, equipment or appliances.

In general, durable goods can be purchased, leased or rented. In the case of leasing, the two parties involved in the transaction are the lessor and the lessee (the person or enterprise that uses the good in leasing). In exchange for the transfer of user rights, the lessor receives payments. Leasing, contrary to renting, often foresees the possibility of the acquisition of the good at the end of the leasing term; renting is also usually for

¹¹²Cyprus and Poland, 2005; Ireland, Malta and Sweden, incomplete or not available.

shorter periods than leasing. The most important items that are rented or leased include transport equipment (motor vehicles, ships, aircraft, etc.) and agricultural, industrial, construction or office equipment.

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers the renting of construction equipment, corresponding to NACE Group 45.5, which is part of the [construction](#) sector. The activities covered in this article are the renting of construction and demolition equipment with an operator, including cranes and mechanical diggers. It does not cover the simple renting of equipment without an operator, which in NACE is classified as Class 71.32 (see the article on [renting and operational leasing](#)).

Main statistical findings

Structural profile

Renting of construction or demolition equipment (NACE Group 45.5) was the smallest NACE group within the [EU-27](#) construction sector (NACE Section F) in terms of the number of [enterprises](#) in the sector, as well as its [employment](#), [turnover](#) and [value added](#); this sector contributed less than 1% to the construction total for each of these measures.

Within the EU-27, the United Kingdom dominated this small sector, with its EUR 1.4 billion of value added equal to 35.0% of the EU-27 total in 2006, and its workforce accounting for 22.0% of the EU-27 total. Spain and the Netherlands were the next largest Member States by both of these measures. In terms of value added, however, Estonia and Slovenia were the only Member States where this activity contributed 0.3% or more to the non-financial business economy total¹¹³.

Expenditure and productivity

Although small in terms of [output](#) and employment, this sector recorded a relatively substantial level of [tangible investment](#). Tangible investment in this sector was valued at EUR 1.3 billion in the EU-27 in 2006, which equated to 2.7% of the total for the construction sector, some 3.5 times as high as its contribution in value added terms. The [investment rate](#), which relates investment to value added, was 32.8% for the renting of construction or demolition equipment, well above the non-financial business economy average of 18.4%. Indeed, the investment rate was the sixth highest among the 149 non-financial business economy NACE groups with 2005 or 2006 data available. To some extent these high investment indicators reflect the nature of this capital-intensive activity.

EU-27 personnel costs accounted for 32.1% of [operating expenditure](#) in this sector in 2005, the highest share among the construction NACE groups. At EUR 28.6 thousand per employee in 2006, average personnel costs were also above the construction average, but were lower than for site preparation (2005). Apparent [labour productivity](#) was EUR 50.0 thousand per person employed, by far the highest level in construction, and this

¹¹³Bulgaria, Poland, Romania and Finland, 2005; Cyprus, Malta and the Netherlands, not available.

resulted in a particularly high [wage-adjusted labour productivity ratio](#) of 175.0%. It should be noted that financial costs and depreciation charges constitute the main cost elements (other than personnel costs) in this activity and these are not considered when calculating gross value added on which these productivity measures are based.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Context

Building and civil engineering projects typically take much longer from conception to completion than in many other sectors, and often involve a large number of sub-contracting enterprises with various specialisations. Construction projects are often a key factor in urban regeneration, and also in maintaining or developing transport and communication infrastructure. Nevertheless, construction projects impact upon the environment in a number of ways, notably the change in land use, the consumption of materials and fuel, the production of waste, as well as noise and air emissions.

Another characteristic of construction activity is that it is particularly cyclical, influenced by business and consumer confidence, interest rates and government programmes. The level of confidence among construction enterprises, according to the [European Commission](#) 's [Directorate-General for Economic and Financial Affairs](#) is presented in terms of a balance of positive compared with negative responses. This measure turned positive in July 2006 for the first time since June 1990, peaked in September 2006 and then became negative again in November 2007. During 2008, the fall in construction confidence accelerated and fell particularly strongly in the final quarter of 2008, such that by December 2008 the balance was down to -32.3%. At the time of writing, with overall economic activity declining in many Member States, major public sector funding for infrastructure projects has been proposed by a number of governments as one means of stimulating activity and creating jobs.

Notes

Repair and installation of machinery and equipment statistics - NACE Rev. 2

Data from April 2012. Most recent data: Further Eurostat information, Main tables and Database .

This article presents an overview of statistics for the repair and installation of machinery and equipment in the [European Union \(EU\)](#) , as covered by [NACE Rev.2 Division33](#). Most manufacturing activities involve the production of a good or industrial services that transform intermediate goods (such as the coating of metals); in contrast, the repair and installation activities covered in this article are industrial services that generally relate to new or existing capital goods.

Main statistical findings

Structural profile

The EU-27's repair and installation of machinery and equipment sector (Division33) included 156 thousand enterprises in 2009. These enterprises employed 1.2 million persons and generated EUR50000 million of value added, equivalent to 0.9% of the non-financial business economy (Sections B to J and L to N and Division95) total for both indicators. The repair and installation of machinery and equipment sector contributed 3.9% of employment in manufacturing (Section C) and 3.6% of manufacturing value added.

The apparent labour productivity of the EU-27's repair and installation of machinery and equipment sector in 2009 was EUR40 thousand per person employed, just below the non-financial business economy average (EUR41.6 thousand per person employed) and EUR6 thousand per person employed less than the manufacturing average (EUR46 thousand per person employed). Despite relatively low apparent labour productivity, average personnel costs within the EU-27's repair and installation of machinery and equipment sector were quite high, at EUR40.0 thousand per employee. Average personnel costs in the repair and installation of machinery and equipment sector were one third higher than the non-financial business economy average and also well above the EUR34.5 thousand per employee average for manufacturing.

The repair and installation of machinery and equipment was one of only two manufacturing NACE divisions in 2009 to record apparent labour productivity below the manufacturing average accompanied by average personnel costs above the manufacturing average – the other was the manufacture of motor vehicles, trailers and semi-trailers (Division29). The consequence of relatively low apparent labour productivity and high average personnel costs was a low wage-adjusted labour productivity ratio: the 104.2% ratio recorded for the EU-27's repair and installation of machinery and equipment sector was the lowest among manufacturing NACE divisions in 2009 and the fifth lowest among all non-financial business economy NACE divisions for which data are available.

In contrast, the EU-27's repair and installation of machinery and equipment sector recorded a gross operating rate of 8.0% in 2009, which placed this sector between the manufacturing average (7.0%) and the non-financial business economy average (9.7%) for this measure of operating profitability.

Sectoral analysis

The repair of fabricated metal products, machinery and equipment (Group33.1, hereafter referred to as repair) was the largest of the two subsectors in the EU-27 in 2009, contributing two thirds of the sector's value added and employing nearly three quarters of the workforce; the remaining shares were accounted for by the installation of industrial machinery and equipment subsector (Group33.2, hereafter referred to as installation).

The two subsectors registered quite different levels of apparent labour productivity within the EU-27 in 2009: the EUR38 thousand per person employed for the repair subsector was below the non-financial business economy average (EUR41.6 thousand) while the EUR49 thousand per person employed for the installation subsector was above the manufacturing average (EUR46 thousand). However, both subsectors recorded average personnel costs above the manufacturing average, though the average for repair (EUR35.4 thousand) was considerably lower than that for installation (EUR43.9 thousand).

The relatively high gross operating rate for the whole of the EU-27's repair and installation of machinery and equipment sector in 2009 was pulled upwards by the repair subsector where the gross operating surplus was equivalent to 9.4% of turnover, very close to the non-financial business economy average (9.6%). In contrast, the gross operating rate for the installation subsector was 5.6%, below the manufacturing average (7.0%).

Country analysis

In value added terms, France was the largest Member State in the repair subsector in 2009, with one fifth (19.9%) of the EU-27 total. Germany had the highest value added in the installation subsector with a 29.7% share of the EU-27 total. In the repair and installation of machinery and equipment sector as a whole Germany's share of EU-27 value added was marginally greater than that of France, 23.4% compared with 22.1%. These two shares were approximately double the shares recorded for the United Kingdom (11.7%) and Italy (11.6%). The relative importance of the repair and installation of machinery and equipment was highest in France, as this sector contributed 1.4% of non-financial business economy value added; the next most specialised Member States were Poland (1.2%) and Latvia (1.1%). By the same measure, by far the least specialised Member States were Luxembourg, Cyprus and Ireland where this sector contributed 0.2% or less of non-financial business economy value added in 2009.

All Member States recorded a relatively low wage-adjusted labour productivity ratio in the repair and installation of machinery and equipment sector in 2009: none of the Member States recorded a ratio for this sector that reached the average for their non-financial business economy as a whole and for Sweden and Lithuania the wage-adjusted labour productivity ratio for the repair and installation of machinery and equipment was below 100%. For the gross operating rate a minority of Member States recorded a higher rate for the repair and installation of machinery and equipment sector than for their national non-financial business economy as a whole.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the repair and installation of machinery and equipment sector in the EU, as covered by NACE Rev.2 Division33. The repair and maintenance of machinery and equipment includes specialised repair of manufactured goods with the aim to restore machinery, equipment and other products to working order. The provision of general or routine maintenance (in other words, servicing) on such products to ensure they work efficiently and to prevent breakdown and unnecessary repairs is also included, as is the specialised installation of machinery.

This NACE division is composed of two groups:

- the repair of fabricated metal products, machinery and equipment (Group33.1);
- the installation of industrial machinery and equipment (Class33.20).

This division only includes specialised repair and maintenance activities: note that a substantial amount of repair is also done by manufacturers of machinery, equipment and other goods themselves. Equally, rebuilding or remanufacturing of machinery and equipment is not included and is classified elsewhere in manufacturing. Also excluded from the statistics presented in this article is the cleaning of industrial machinery (which forms part of [services to buildings and landscape activities](#) , Division81), as well as the repair and maintenance of goods that are utilised as capital goods and consumer goods (for example, office and household furniture repair) which is typically classified as part of the [repair and maintenance of household goods](#) (Division95). The installation of equipment that forms an integral part of buildings or similar structures, such as the installation of electrical wiring, the installation of escalators or air-conditioning systems, is classified as part of [construction](#) (SectionF).

Repair of personal and household goods statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers the repair of personal and household goods, corresponding to NACE Group 52.7, which is part of the [retail trade and repair](#) sector. The activities covered in this article are the repairing of:

- footwear;
- electrical goods;
- clocks and watches;
- piano-tuning.

This article covers specialist repairers only, and excludes enterprises that carry out repair as a secondary activity in combination with other activities.

	Enterprises (thousand)	Turnover (EUR million)	Value added (EUR million)	Persons employed (thousand)	Share in total (%)	
					Value added	Persons employed
Repair of personal and household goods	135.7	11 695	4 795	255.3	100.0	100.0
Repair of boots, shoes and other articles of leather	:	1 063	512	36.4	10.7	14.3

Source: Eurostat (SBS)

Table 2: Repair of personal and household goods (NACE Group 52.7). Structural profile: ranking of top five Member States in terms of value added and persons employed, 2006

The repair of personal and household goods sector (NACE Group 52.7) differs from all of the other activities in the retail trade and repair sector in that it is not a retail activity, and as such does not consist in buying and selling goods. Within the [EU-27](#) this sector had a population of 135.7 thousand [enterprises](#) in 2006 which [employed](#) 255.3 thousand persons and generated EUR 4.8 billion of [value added](#), with tangible investment valued at EUR 311.9 million. By all of these measures this was the second smallest sector within retail trade and repair (NACE Division 52), larger only than the [retail sale of second-hand goods in stores](#).

An analysis at the NACE class level shows that the repair of electrical household goods (NACE Class 52.72) and the miscellaneous activity of repair not elsewhere classified (NACE Class 52.74) were the two largest subsectors,

together responsible for around four fifths of the sector's value added and employment in the EU-27.

Of the five largest Member States, the United Kingdom had the smallest workforce in the repair of personal and household goods sector, but generated the most value added. However, none of the larger Member States¹¹⁴ were particularly specialised in this sector, and only Greece and Cyprus generated 0.2% or more of their non-financial business economy value added through the repair of personal and household goods.

The [wage-adjusted labour productivity ratio](#) for the EU-27's repair of personal and household goods sector was 101.1% in 2006, indicating that apparent [labour productivity](#) was only marginally higher than average [personnel costs](#). This was the second lowest wage adjusted labour productivity ratio among all of the [non-financial business economy](#) NACE groups (with 2005 or 2006 data available), higher only than for [retail sales not in stores](#)). In only 12 of the Member States¹¹⁵ for which data are available was the wage adjusted labour productivity ratio for these activities above 100%.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Context

Retailing is typically the final stage of distribution between producers and consumers. Since the development of the Internet, there has been an increasing use of commerce via the web. As such, there has been a gradual shift from traditional methods of purchasing from stores or markets to purchasing remotely. According to Eurostat's information society statistics, some 12% of the turnover of distributive trades (including motor trades (NACE Division 50) and wholesale trades (NACE Division 51), as well as retail trade and repair) enterprises with ten or more persons employed was derived from [e-commerce](#) in 2008. According to the same source, one quarter of the EU-27's population ordered or bought goods or services for private use through the Internet in 2008 (during the three months preceding the survey). Note that these figures refer to goods and services supplied to individuals by all sectors of the economy, not just enterprises that are specialised in retail sales.

In October 2008, the [European Commission](#) put forward a [proposal COM\(2008\) 614](#) for a Directive on consumer rights, to try to make purchases easier and safer, whether in-store or not. The proposal covers the provision of price information, protection against late delivery and non delivery, as well as setting out rights on issues such as cooling-off periods, returns, refunds, repairs and guarantees and unfair contract term.

Notes

Research and development sector statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article introduces a [set of statistical articles](#) which analyse the structure, development and characteristics of the economic activities in the research and development sector in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), this sector covers NACE Division 73, and its activities are treated in more depth in two further articles which cover research and experimental development within different fields of investigation:

- natural sciences and engineering (NACE Group 73.1);
- social sciences and humanities (NACE Group 73.2).

Note that market research activities are not covered and that these are included as part of [Funds and asset management statistics - NACE Rev. 1.1](#). Furthermore, it should be noted that the statistics presented for the research and development sector in this article concern exclusively those enterprises whose main activity consists of carrying out research and development activities, and thus excludes research and development departments of universities, public administrations and enterprises whose main activity is otherwise classified.

Source: Eurostat (SBS)

Table 3: Research and development (NACE Division 73). Main indicators, 2006 (1)

In 2007, research and development expenditure in the EU-27 amounted to more than EUR 226 billion, compared with EUR 215 billion in 2006 and EUR 170 billion in 2000. Together, Germany (EUR 61 billion), France (EUR 39 billion) and the United Kingdom (EUR 34 billion, 2006) accounted for 60% of total research and development expenditure in the EU-27. The EU-27's research and development intensity in 2007 was 1.83%, practically unchanged compared with the ratios of 1.84% recorded in 2006 and 1.85% in 2000. In 2007 research and development intensity varied among the Member States from 0.45% of GDP in Cyprus to 3.64% in Sweden. Finland (3.47%) was the only other Member State to record research and development intensity over 3%, with Austria (2.56%), Denmark (2.55%) and Germany (2.53%) the next closest to this threshold. The highest relative increases in research and development intensity between 2000 and 2007 were in Cyprus (from 0.24% to 0.45%) and Estonia (from 0.61% to 1.14%).

Structural profile

Approximately 400.0 thousand persons worked in the 40.7 thousand enterprises in the EU-27's research and development sector (NACE Division 73) in 2006, accounting for just 0.3% of the non-financial business economy (NACE Sections C to I and K) workforce. Paid employees accounted for a high proportion (93.0% in 2005) of the persons employed in this sector in the EU-27. Value added reached EUR 400 billion in 2005, around 0.4% of the non-financial business economy total. In terms of employment and value added the research and development sector was the smallest of all structural business statistics sectors.

The United Kingdom and Germany dominated this sector, combining to generate more than half (55.6%) of the value added in the EU-27 and to provide close to half (49.3%) of the employment. France was the only other Member State with a double digit share of the EU-27's value added or employment in this sector. Only in a few Member States¹¹⁶ did this sector's contribution to non-financial business economy value added approach or exceed 0.5% in 2006, notably in the United Kingdom (0.6%), Slovenia and Romania (both 0.5%). The relatively high specialisation of the Netherlands in this sector can be seen from a similar analysis based on employment, as 0.7% of Dutch employment in the non-financial business economy was in the research and development sector in 2005. Continuing this analysis of the relative importance of the research and development sector in terms of its contribution to non-financial business economy employment (see map), there are many regions where this sector's contribution was close to zero. Only in Voreio Aigaio (Greece) did this sector's share of non-financial business economy employment exceed 2%, and in fact there it reached 4.8%. Most of the regions where this sector contributed more than 0.5% of the non-financial business economy employment were in the United Kingdom, Germany or the Netherlands.

Large enterprises dominated the EU-27's research and development sector, accounting for close to three fifths (58.3%) of the value added in 2006, compared with their contribution of just over two fifths (42.1%) for the non-financial business economy as a whole. In relative terms the contribution of **medium-sized enterprises** was even greater, as they generated close to one quarter (24.5%) of the research and development sector's value added in 2006, compared with an average of 17.8% for the non-financial business economy (in 2005).

Employment characteristics

The research and development sector's workforce in the EU-27 was atypical of a services sector, at least in terms of the share of full-time workers: in 2007, some 86.6% of the sector's workforce was employed full-time, slightly above the non-financial business economy average, and 6.9 percentage points above the non-financial services (NACE Sections G to I and K) average of 79.7%. An analysis of the workforce in terms of gender shows that in this respect the research and development sector is typical of a services activity, with male employment accounting for 55.4% of the sectoral total, very close to the non-financial services average and 9.5 percentage points below the non-financial business economy average. In several Member States the proportion of men and women in research and development sector's workforce was almost the same: the share of men was at its lowest¹¹⁷ in Bulgaria, just 38.2%.

In terms of age profile, there was a much higher proportion of the research and development sector's workforce that were aged 50 or over (25.6%) than the average for the non-financial business economy (21.9%), and also a slightly higher proportion of persons aged 30 to 49. Consequently only a relatively small proportion of the research and development sector's workforce was made up of younger workers aged less than 30.

Expenditure, productivity and profitability

The EU-27's research and development sector recorded gross **tangible investment** valued at approximately EUR 3.7 billion in 2005, around 0.4% of the total in the non-financial business economy. In 2006, the two largest Member States in this sector, namely the United Kingdom and Germany, recorded the highest levels of investment, EUR 1.4 billion in the United Kingdom and EUR 0.9 billion in Germany, combining to account for close to three fifths of the total EU-27 investment in this sector.

Personnel costs accounted for a high proportion (40.0%) of **operating expenditure** in the EU-27's research and development sector in 2006. This was approximately two and a half times the average proportion within the non-financial business economy, and the second highest proportion (lower only than for the extraction of oil and gas) among the non-financial business economy NACE divisions. This can to some extent be explained by high average personnel costs, which were EUR 50.0 thousand per employee, compared with a non-financial business economy average of EUR 28.8 thousand per employee: the high average personnel costs reflect the relatively highly qualified nature of the workforce.

In 2005, the apparent **labour productivity** of the EU-27's research and development sector was EUR 55.0

¹¹⁶Bulgaria, Cyprus, Poland and Romania, 2005; Luxembourg, Malta, the Netherlands and Sweden, not available.

¹¹⁷Lithuania, 2006; Estonia, Ireland, Cyprus, Malta and Portugal, not available.

thousand per person employed, which when compared with the high average personnel costs resulted in a [wage-adjusted labour productivity ratio](#) of 110.0%. This was the lowest wage-adjusted labour productivity ratio among the non-financial business economy NACE divisions in 2005 or 2006. Due to negative value added in this sector in 2006, Ireland recorded a negative wage-adjusted labour productivity ratio, while a further seven Member States¹¹⁸ recorded ratios below parity (100%) indicating that average personnel costs outstripped apparent labour productivity, with the lowest ratio (55.2%) in Denmark. None of the Member States recorded a wage-adjusted labour productivity ratio in the research and development sector that was higher than the average ratio for their respective non-financial business economies. Equally, this sector recorded a low [gross operating rate](#), as the [gross operating surplus](#) (value added less personnel costs) represented 8.0% of [turnover](#) in 2005, 2 percentage points below the EU-27 non-financial business economy average. Along with Ireland, several other Member States recorded negative gross operating rates (indicating that value added was less than personnel costs) for the research and development sector, notably Denmark, Finland and the United Kingdom.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include the [Labour force survey \(LFS\)](#).

Context

Research funding in the EU is organised around multi-yearly programmes. The seventh framework programme for research and technological development for the period 2007 to 2013 (FP7) has funding amounting to around EUR 51 billion. FP7 will be implemented through specific programmes corresponding to the main themes of European research policy.

In April 2007, the [European Commission](#) adopted a Green paper titled 'The European Research Area: New Perspectives' ([COM\(2007\) 161](#)). This opens discussions on a number of issues, notably the mobility of researchers, developing research infrastructure and institutions; as well as improvements in the circulation and sharing of knowledge, research programmes, and global research cooperation. It aims to tackle underinvestment and fragmentation. The principles of the overall governance of the [European Research Area \(ERA\)](#) are known as the 'Ljubljana Process' stemming from discussions in Ljubljana and Brdo (Slovenia) in April 2008. Five initiatives for the ERA have been foreseen, with several already adopted in 2008; these concern researchers, research infrastructure, knowledge sharing, joint programming, and international science and technology cooperation.

Increased levels of research and development expenditure are seen as one of the means to achieve the goals set out by the [European Council](#) in Lisbon in 2000: in 2002 a target was set that research and development intensity (research and development expenditure relative to GDP) should reach 3% by 2010.

Notes

Restaurants, bars and catering statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers restaurant, bars and catering, corresponding to NACE Groups 55.3, 55.4 and 55.5, which are part of the [hotel, restaurant and catering services](#) sector. The activities covered in this article are the sale of meals and beverages for consumption at:

- restaurants, corresponding to NACE Group 55.3
- bars, corresponding to NACE Group 55.4
- canteens and catering, corresponding to NACE Group 55.5

This article covers the sale of food and beverages to final consumers that may be tourists or local customers. Included, for example, are:

- fast-food stands;
- take away restaurants;
- self-service outlets;
- traditional restaurants;
- pubs;
- bars;
- cafes;
- catering enterprises which generally operate on a business-to-business basis.

It is important to bear in mind that only [enterprises](#) for which the provision of drinks and meals is the principal activity are covered by the statistics presented in this article. Enterprises offering food and drink as a complement to their core business are not included, and in some cases, meals and beverages may represent a significant secondary activity – for example, the sale of food and beverages in cinemas or recreation parks (if these are not operated by separate enterprises).

	Highest value added (1)		Largest number of persons employed (1)		Most specialised: share in non-financial business economy (%) (2)

Source: Eurostat (SBS)

Table 1: Restaurants, bars and catering (NACE Groups 55.3, 55.4 and 55.5). Structural profile: ranking of top five Member States in terms of value added and persons employed, 2006

Main statistical findings

Structural profile

More than 1.4 million enterprises were active in the restaurants, bars and catering sector (NACE Groups 55.3 to 55.5) in the EU-27 in 2006. The labour-intensive nature of restaurants, bars and catering activities was reflected through the 7.0 million persons employed in the EU-27 in 2006, three quarters of the accommodation and food services (NACE Section H) workforce. However, it should be kept in mind that this figure is based on head-counts of persons employed and does not take into account the seasonal or part-time nature of many positions. The restaurants, bars and catering sector had a particularly low share of paid employees, just 79.6%, indicating that approximately one fifth of the persons employed in this sector were working proprietors or unpaid family workers.

Restaurants, bars and catering enterprises generated a total of EUR 298.6 billion of turnover in the EU-27 in 2006, resulting in EUR 116.5 billion of value added; these indicators represented around two thirds of the accommodation and food services total. The United Kingdom had by far the largest restaurants, bars and catering sector within the EU-27, both in terms of value added and employment. Unsurprisingly, given its large share of the EU-27 value added total, the United Kingdom was one of the most specialised Member States¹¹⁹ in these activities. Restaurants, bars and catering generated 2.7% of the total value added in the United Kingdom's non-financial business economy, the fourth highest share among the Member States, slightly less than in Spain and Portugal, although less than half the share in Cyprus (6.1%). The least specialised Member State, by quite a large margin, was Slovakia, where just 0.4% of non-financial business economy value added was generated by restaurants, bars and catering enterprises.

Expenditure and productivity

Gross tangible investment by EU-27 restaurants, bars and catering enterprises amounted to EUR 15.7 billion in 2006, less than half of the total for accommodation and food services. The investment rate in the restaurants, bars and catering sector was 13.5%, some 4.8 percentage points lower than the non-financial business economy average, and less than half the rate recorded for accommodation services.

The apparent labour productivity and average personnel costs of the EU-27's restaurants, bars and catering sector were both extremely low, explained, to a large extent, by a high degree of part-time work. Apparent labour productivity in the restaurants, bars and catering sector was EUR 16.7 thousand per person employed in 2006, while average personnel costs were EUR 14.1 thousand per employee. When compared with the NACE groups within the non-financial business economy (with data available for 2005 or 2006) there were very few with lower values for these two indicators in 2006, only in some of the textiles, clothing and leather manufacturing activities and in industrial cleaning. The resulting wage-adjusted labour productivity ratio for the restaurants, bars and catering sector was 118.5%, considerably below the ratio for accommodation services (146.5%).

Greece, Italy and Hungary all recorded a wage adjusted labour productivity ratio below parity (100%) in the restaurants, bars and catering sector in 2006, indicating that average personnel costs were higher than the apparent labour productivity in these Member States¹²⁰. Only in one Member State, Ireland, was the wage adjusted labour productivity ratio higher in the restaurants, bars and catering sector than in the accommodation services sector.

Data sources and availability

The main part of the analysis in this article is derived from structural business statistics (SBS), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

¹¹⁹Bulgaria, Cyprus, Poland and Romania, 2005; Malta and the Netherlands, not available.

¹²⁰Cyprus and Poland, 2005; Malta, not available.

Context

One of the main characteristics of tourism is the high income elasticity of demand, which increases or reduces more easily than for many other products or services. As such, spending on tourism generally decreases proportionally faster than consumers' income during times of economic slowdown. Moreover, political or economic uncertainties tend to lead to a diversion of tourism demand, leading for example to shifts between outbound tourism and domestic tourism, for example when exchange rates change rapidly. Furthermore, a downturn in economic fortunes is also likely to result in reduced business activity; likely to be reflected in fewer business trips and nights spent in hotels, as well as less business lunches and dinners.

Retail trade and repair statistics - NACE Rev. 1.1

Data from January 2009. Most recent data: Further Eurostat information, Main tables and Database

This article introduces a [set of statistical articles](#) which analyse the structure, development and characteristics of the economic activities in the retail trade and repair sector in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), this sector covers NACE Division 52, which is the retailing and repair of personal and household goods, and comprises the resale without transformation of new and used goods to the general public for personal or household use and consumption. The activities of this sector are treated in more depth in six further articles:

- [Non-specialised in-store retail trade](#) ;
- [Specialised in-store food retail trade](#) ;
- [Specialised in-store non-food retail trade](#) ;
- [Second-hand goods in-store retail trade](#) ;
- [Non-store retail trade](#) ;
- [Repair of personal and household goods](#) .

Note that the retail trade and repair sector does not include the [retail trade of motor vehicles, motorcycles or automotive fuel \(NACE Division 50\)](#), nor the renting and hiring of personal and household goods to the public.

Table 5: Retail trade and repair (NACE Division 52). Main indicators, 2006 (1)

Main statistical findings

Structural profile

The [enterprise](#) population of the [EU-27](#) 's retail trade and repair (NACE Division 52) sector was around 3.8 million in 2006, close to one fifth (18.8%) of all enterprises in the [non-financial business economy](#) (NACE Sections C to I and K). These enterprises [employed](#) 17.5 million persons, 13.5% of the non-financial business economy workforce. With a 79.7% share of paid employees in persons employed in 2006, the EU-27 retail trade and repair sector posted the second highest proportion of self-employed and unpaid family workers of all the non-financial business economy NACE divisions, just after real estate activities (NACE Division 70).

The retail trade and repair sector's [turnover](#) was valued at EUR 2271.8 billion, from which EUR 418.4 billion [value added](#) was generated, equivalent to 10.2% and 7.4% of the non-financial business economy total. From these shares the main characteristics of the retail trade and repair sector can be derived: there were a very large number of enterprises, having a small average size, producing relatively high turnover but less value added, with a low apparent [labour productivity](#) . The retail trade and repair sector was the second largest of the structural business statistics sectors in terms of its number of enterprises, the size of its workforce, and its turnover – only lower than for business services (see [Business services statistics - NACE Rev. 1.1](#)) for the first two measures, and only lower than for wholesale trade (see [Wholesale trade statistics - NACE Rev. 1.1](#)) in terms of turnover; in value added terms, retail trade and repair was the fourth largest sector.

Based on an analysis at the level of the activities presented in the six sub-sectors of the retail trade and repair sector, specialised in-store new goods retailing other than food (NACE Groups 52.3 and 52.4) and non-specialised in-store retailing (NACE Group 52.1) were the largest retail activities, using the measures of value added and employment. Specialised in-store new goods retailing other than food generated more than half (53.8%, in 2005) of the EU-27's retail trade and repair sector's value added and employed close to half (49.0%) of the sectoral workforce.

With EUR 87.1 billion of value added, the United Kingdom was the largest contributor to the EU-27's retail trade and repair sector in 2006, followed by Germany (EUR 76.1 billion), and these two Member States had the largest workforces in this sector, approaching 3 million persons in each country. As a share of the non-financial business economy value added total, the retail trade and repair sector was the largest in Greece (12.0% of the national total) and Cyprus (10.1%). This sector contributed relatively high proportions to the national non-financial business economy workforce, particularly in Greece where it reached one fifth of the total – it should be noted that the high contributions of the retail trade and repair sector to non-financial business economy employment in many Member States are affected by the importance of part-time employment in this sector (see below).

The specialisation in each region (in some cases the whole country is treated as one region) can be seen from the map which shows the contribution of retail trade and repair employment to the non-financial business economy workforce. Even in the region with the highest share of non-financial business economy employment concentrated in the retail trade and repair sector, 27.1% in Dytiki Ellada (Greece), this share was less than 3.5 times as high as the region with the lowest share, 7.8% in Západné Slovensko (Slovakia); this was a lower range than for any of the other maps shown in the structural business statistics sector articles. The specialisation of Greece in this sector is emphasised by the presence of seven Greek regions among the ten most specialised within the EU.

Annual [short-term statistics](#) show the development of this sector over several years. Between 1998 and 2007 the index of employment for retail trade and repair followed a roughly similar path to that for non-financial services (NACE Sections G to I and Divisions 72 and 74) as a whole, with slower growth at the beginning and end of this period. As a result, retail trade and repair employment grew by 1.8% per year, on average, between 1998 and 2007, whereas the rate for non-financial services was 2.3% per year.

The EU-27's turnover index for retail trade and repair rose every year between 1997 and 2007, with growth rarely below 3%, reaching a maximum of 5.0% in 2001. Turnover indices are also available for the four largest retail trade NACE groups (Groups 52.1 to 52.4), with a time series starting at least in 1998 for each of these activities. Over the period 1998 to 2007, turnover growth for retail trade and repair in the EU-27 averaged 3.6% per year, with the rate for specialised retailing of food, beverages and tobacco less than half this rate (1.4%), while the retailing of pharmaceuticals, medical goods, cosmetics and toiletries was well above (4.8%).

Average turnover per enterprise in the EU-27 varied greatly between the various parts of the retail trade and repair sector in 2006, ranging from EUR 1.5 million (2005) for non-specialised in-store retailing to less than one tenth of this size (EUR 123.2 thousand) for second-hand goods retailing (NACE Group 52.5); unsurprisingly, the repair of personal and household goods (NACE Group 52.7), which is not a retail trade activity, recorded

an even lower average turnover per enterprise (EUR 86.2 thousand).

A size class analysis for the EU-27's retail trade and repair sector for 2006 shows that **small and medium-sized enterprises** (SMEs, enterprises with less than 250 persons employed) generated 56.4% of retail trade and repair value added and 65.1% of the sector's employment. These shares were broadly comparable with the averages recorded for the whole of the non-financial business economy.

However, among SMEs, the contribution of **micro**, small and medium-sized enterprises was distinctly different in the retail trade and repair sector than in the non-financial business economy. Micro enterprises (with less than 10 persons employed) accounted for close to one third of retail trade and repair value added, and over two fifths of employment, well above the non-financial business economy averages. As a result, the contribution of **small enterprises** (with 10 to 49 persons employed) and medium-sized enterprises (with 50 to 249 persons employed) to retail trade and repair value added was below the non-financial business economy average, particularly in the case of **medium-sized enterprises**. As such, the retail trade and repair sector can be characterised as having a dominant micro enterprise subpopulation, alongside a significant subpopulation of large enterprises.

Focus on retail trade turnover Specialised in-store retailing (NACE Groups 52.2 to 52.5) generated just over half (52.4%) of retail trade (NACE Groups 52.1 to 52.6) turnover in 2006 in the EU (based on data for 25 of the Member States¹²¹), while non-specialised in-store retailing (NACE Group 52.1) generated 43.0% of the total. Retailing not in-stores (NACE Group 52.6) accounted for the remainder (4.6%). Germany, where mail order sales were particularly high, topped the rankings for this latter type of retailing, with 8.5% of German retail trade turnover derived outside of stores.

In 12 of the 25 Member States with data available at least half of retail trade turnover was generated by specialised in-store retailers, while non-specialised in-store retailers generated half or more of retail trade turnover in just three Member States – Slovenia, Finland and Lithuania. The highest share for specialised in-store retailers was 66.0% in Greece.

However, underlying the relatively even split between specialised and non-specialised in-store retail turnover are two quite different situations, when food, beverage and tobacco products are separated from all other new products. For food, beverages and tobacco products non-specialised retailers (NACE Class 52.11) were dominant relative to specialised retailers (NACE Group 52.2) in every Member State. In the EU (again based on an average for 25 of the Member States¹²²), only 13.7% of turnover was recorded in specialised food, beverages and tobacco retailers, a share that fell to 5% or less in the Baltic Member States and Slovenia. At the other end of the spectrum, specialised retailers generated relatively high shares of turnover in some of the southern Member States – particularly in Greece and Spain – as well as in Poland and Austria.

In contrast, the in-store retailing of other new products was dominated by specialised retailers. Only in Finland (24.3%) and Slovakia (34.5%) did the share of non-specialised retailers exceed even one fifth of total turnover for new goods other than food, beverages and tobacco, while the average for the EU (based on data for 24 of the Member States¹²³) was 9.3%.

Employment characteristics

According to results from the **Labour force survey**, a high proportion of the EU-27's retail trade and repair workforce were women (62.2%) in 2007. This split between male and female workers was almost a mirror image of the average for the non-financial business economy, where 35.1% of workers were female. The retail trade and repair workforce had the second highest proportion of women in its workforce among all of the NACE divisions that make up the non-financial business economy, only less than for clothing manufacturing activities (NACE Division 18, see **Textile production statistics - NACE Rev. 1.1**). The female share of retail trade and repair employment was systematically higher than the average recorded for the non-financial business economy in each of the Member States, rising to over twice as high in Luxembourg, Slovakia and Poland.

There was also a high incidence of part-time work (28.9% of the workforce) in the EU-27's retail trade and

¹²¹EU average; Bulgaria, Luxembourg and Poland, 2005; excluding Malta and the Netherlands.

¹²²EU average; Bulgaria, Luxembourg and Poland, 2005; excluding Denmark and Malta.

¹²³EU average; Bulgaria and Poland, 2005; excluding Denmark, Malta and the Netherlands.

repair sector in 2007, just over double the non-financial business economy average (14.3%). The proportion of part-time employment in retail trade and repair activities was the highest among all of the NACE divisions that constitute the non-financial business economy. In relative terms, high part-time employment in this sector was particularly evident in Slovakia, the Nordic Member States, Ireland and the United Kingdom, where the part-time employment rate was at least 2.3 times as high as the national non-financial business economy average.

There was also a particularly high number of young persons employed in the EU-27's retail trade and repair workforce in 2007, as 31.2% of those employed were aged between 15 and 29, compared with the 24.3% average for the non-financial business economy. The retail trade and repair sector reported the second highest share of younger workers among all the NACE divisions of the non-financial business economy¹²⁴, below the share recorded for hotels and restaurants. As a consequence the shares of the two other age groups were below average; persons aged 30 to 49 accounted for less than half the retail trade and repair workforce, making this one of only two non-financial business economy NACE divisions where this was the case.

Expenditure, productivity and profitability

Typically for a distributive trade activity, the level of **gross investment in tangible goods** was low in the retail trade and repair sector, EUR 61.3 billion in the EU-27 in 2006. This was equivalent to 5.9% of non-financial business economy total investment, and resulted in an investment rate (gross tangible investment as a percentage of value added) of 14.7%, higher than the two other distributive trades sectors, but still 3.7 percentage points below the non-financial business economy average. Among the retail trade and repair NACE groups only non-specialised in-store retailing recorded an **investment rate** above the non-financial business economy average, reaching 20.4%. A small number of Member States recorded an investment rate in the retail trade and repair sector that were above their national non-financial business economy averages, notably Slovenia where the investment rate in this sector reached 47.4%.

Also characteristic of an activity within distributive trades was the low share of **personnel costs** in total operating expenditure: the retail trade and repair sector's personnel costs represented 12.3% of **operating expenditure**, admittedly higher than in motor or wholesale trades, but below the 16.1% non-financial business economy average. The subsector concerning the repair of household goods (NACE Group 52.7) was the main exception for this indicator, as personnel costs amounted to 26.8% of the operating expenditure total. It should be noted that any analysis of personnel costs only reflects the cost of paid employees, and that the proportion of paid employees in the total number of persons employed within the retail trade and repair sector was relatively low. Furthermore, care should be taken when comparing ratios based on simple head counts across Member States or activities because of the high incidence of part-time employment in the retail trade and repair sector. Average personnel costs in the retail trade and repair sector were EUR 18.7 thousand per employee in 2006 and apparent labour productivity was EUR 23.9 thousand per person employed. An analysis of the **wage-adjusted labour productivity ratio** that combines these two ratios reduces the impact of the high rate of part-time employment. This ratio was 128.1% for the EU-27's retail trade and repair sector in 2006, well below the level recorded in the other two distributive trades sectors and also far below the 151.1% average for the non-financial business economy. Two of the subsectors had particularly low wage-adjusted labour productivity ratios, namely retailing not in stores (NACE Group 52.6) and the repair of household goods, which registered ratios of 96.9% and 101.1% respectively: in the first of these two subsectors apparent labour productivity was less than average personnel costs (giving a ratio below 100%), while in the second it was only marginally higher. In fact, these two were the two lowest wage-adjusted labour productivity ratios recorded by any NACE groups within the non-financial business economy in 2006.

All of the Member States¹²⁵ recorded a wage-adjusted labour productivity ratio for their retail trade and repair sector below the average for their non-financial business economy: in the case of Italy a ratio of just 96.4% was recorded, while in Greece the ratio was 98.8%, in both cases indicating that average personnel costs exceeded apparent labour productivity.

Profitability for the EU-27's retail trade and repair sector, here measured by the **gross operating rate**, was 7.0% in 2006, higher than in the two other distributive trades sectors, but still below the average rate for the non-financial business economy (10.8%), influenced as for all distributive activities by the high levels of turnover. Unsurprisingly, as it is not a retail trade activity, the subsector concerning the repair of household goods recorded the highest gross operating rate in 2006, 19.5%.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include [short-term statistics \(STS\)](#) and the [Labour force survey \(LFS\)](#) .

Context

Retailing is typically the final stage of distribution between producers and consumers. Since the development of the Internet, there has been an increasing use of commerce via the web. As such, there has been a gradual shift from traditional methods of purchasing from stores or markets to purchasing remotely. According to Eurostat's information society statistics, some 12% of the turnover of distributive trades (including motor trades (NACE Division 50) and wholesale trades (NACE Division 51), as well as retail trade and repair) enterprises with ten or more persons employed was derived from [e-commerce](#) in 2008. According to the same source, one quarter of the EU-27's population ordered or bought goods or services for private use through the Internet in 2008 (during the three months preceding the survey). Note that these figures refer to goods and services supplied to individuals by all sectors of the economy, not just enterprises that are specialised in retail sales.

In October 2008, the [European Commission](#) put forward a proposal for a Directive on consumer rights ([COM\(2008\) 614](#)), to try to make purchases easier and safer, whether in-store or not. The proposal covers the provision of price information, protection against late delivery and non delivery, as well as setting out rights on issues such as cooling-off periods, returns, refunds, repairs and guarantees and unfair contract term.

Notes

Retail trade statistics - NACE Rev. 2

Data from April 2012. Most recent data: Further Eurostat information, Main tables and Database .

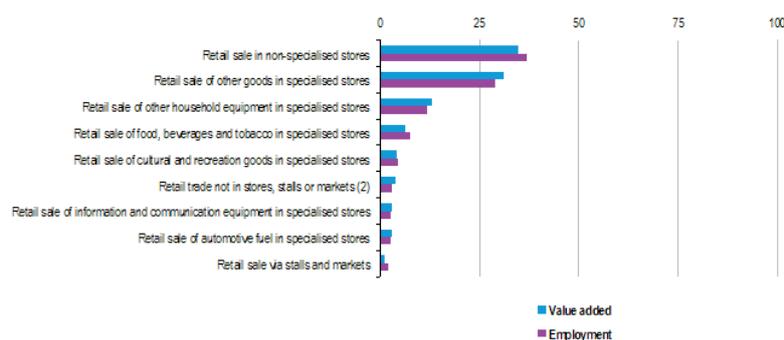

This article presents an overview of statistics for the retail trade sector in the [European Union \(EU\)](#) , as covered by [NACE Rev. 2](#) Division 47. Retailing is typically the final stage of the distribution chain from producers to consumers. Since the development of the internet, there has been an increasing use of web-based commerce. As such, there has been a gradual shift from traditional methods of purchasing from stores or markets towards purchasing remotely.

Main statistical findings

Structural profile

At the NACE division level the retail trade sector (Division47) was the largest within the EU-27's non-financial business economy (SectionsB to J and L to N and Division95) in terms of numbers of enterprises and persons employed and the second largest in terms of turnover and value added, behind wholesale trade (Division46). The EU-27's retail trade sector's turnover was valued at EUR2462.4 billion¹²⁶, from which EUR432.0 billion of value added was generated, equivalent to 11.2% and 7.7% of the totals for the non-financial business economy. There were 3.6 million retail trade enterprises in the EU-27 and they employed 18.5 million persons, equivalent to 17.1% of all enterprises in the non-financial business economy and 13.8% of the non-financial business economy workforce. From these shares the main characteristics of the retail trade sector can be derived: namely, that there were a very large number of enterprises, generally having a small average size, producing a relatively high level of turnover but less value added.

The apparent labour productivity of the EU-27's retail trade sector in 2009 was EUR23 thousand per person employed, well below the non-financial business economy average of EUR41.6 thousand per person employed and the distributive trades average of EUR33 thousand per person employed. This was the lowest apparent labour productivity among the three distributive trades NACE divisions and the fifth lowest (again among NACE divisions) within the non-financial business economy. This low apparent labour productivity was accompanied by low average personnel costs, EUR18.6 thousand per employee, again far below the non-financial business economy and distributive trades averages (EUR30.0 thousand and EUR25.0 thousand per employee respectively) and the sixth lowest level for this ratio among any of the non-financial business economy NACE divisions.

Apparent labour productivity and average personnel costs are both calculated relative to the level of employment based on a head count of workers; there is a relatively high propensity to employ persons on a part-time basis within retail trade and therefore a simple head count of employment over-states the level of labour input when compared with other sectors where part-time employment is less prevalent. The wage-adjusted labour productivity ratio combines the two previous indicators and thereby reduces the impact of the incidence of part-time work. This indicator shows the extent to which value added covers personnel costs, while adjusting for the ratio of paid employees to the total number of persons employed. Although the wage-adjusted labour productivity ratio of 125.0% for the EU-27's retail trade sector in 2009 remained below the non-financial business economy average (138.8%) and the distributive trades average (133.2%), it was much closer, in relative terms, than was the case for apparent labour productivity and average personnel costs.

The gross operating rate (the relation between the gross operating surplus and turnover) was 6.0% for the EU-27's retail trade sector in 2009. Due to the very high turnover inherent in retail trade this rate was relatively low compared with the non-financial business economy average (9.7%), but it was above the distributive trades' average (5.1%).

Sectoral analysis

Within the EU-27 as a whole, retail sale in non-specialised stores (Group47.1) contributed more than one third (34.8%) of retail trade value added in 2009, while retail trade in specialised stores (Groups47.2 to 47.7) accounted for 60.2% and retail sale not in stores (Groups47.8 and 47.9) the remainder. In employment terms, the shares were broadly similar, with a slightly lower share for retail sale in specialised stores and higher shares for the other two aggregates.

Within retail trade in specialised stores, the largest activity in the EU-27 was the retail sale of other goods in specialised stores (Group47.7) with 31.1% of all retail trade value added in 2009 – as such, this activity accounted for more than half of the value added generated in specialised store retailing; it includes, for example, the retailing of clothing, footwear, jewellery, pharmaceuticals, cosmetics, medical products, garden products and second-hand goods. Among the remaining in-store specialised retail activities the largest concerned the retailing of other household equipment (Group47.5), food, beverages and tobacco (Group47.2), and cultural and recreation goods (Group47.6). The two remaining activities for in-store specialised retailing concerned the retail of information and communication (ICT) equipment (Group47.4) and automotive fuel (Group47.3).

¹²⁶A billion is 1000 million.

Retail trade outside of stores was split between retail sale via stalls and markets (Group47.8) which contributed about 1.0% of total retail trade value added and the larger activity of retail trade not in stores, stalls or markets (Group47.9) – which includes, for example, mail-order houses – it contributed 3.8% to total retail trade value added (2008 data).

The low apparent labour productivity figure for the whole of the EU-27's retail trade sector was observed across all of the retail subsectors in 2009, except for retail trade not in stores, stalls or markets which recorded an average of EUR34 thousand of value added per person employed, which was above the distributive trades average. The lowest apparent labour productivity among the nine subsectors was recorded for retail sale via stalls and markets where apparent labour productivity was just EUR11 thousand per person employed, the lowest figure recorded across all of the NACE groups within the non-financial business economy; this particularly low ratio may again be influenced by part-time employment, for example, when trading only takes place a few days a week (market days). Among the seven other subsectors, apparent labour productivity ranged from EUR19 thousand per person employed for the retail sale of food, beverages and tobacco in specialised stores to EUR27 thousand per person employed for the retail sale of information and communication equipment in specialised stores. A ranking of the subsectors according to average personnel costs for the EU-27 showed the same subsectors at each extreme, with average personnel costs per employee ranging from EUR13.4 thousand for retail sale via stalls and markets to EUR26.0 thousand for retail trade not in stores, stalls or markets; the latter was again the only retail trade subsector to record a value above the distributive trades average.

As noted above, the wage-adjusted labour productivity ratio is less influenced by the incidence of part-time employment. Nevertheless, the EU-27 retail sale via stalls and markets subsector still recorded the lowest value by far (81.4%), which was the second lowest among all NACE groups within the non-financial business economy in 2009, higher only than for building completion and finishing (Group43.3). The remaining eight retail trade subsectors recorded EU-27 wage-adjusted labour productivity ratios above 100% in 2009, ranging from 113.2% for the retail sale of other household equipment in specialised stores to 150.7% for the retail sale of automotive fuel in specialised stores; the latter was the only retail trade subsector where the wage-adjusted labour productivity ratio exceeded the average ratios for distributive trades and the non-financial business economy.

Whereas the retail sale via stalls and markets subsector recorded the lowest productivity ratios within the EU-27's retail trade sector in 2009, it also recorded the highest gross operating rate (16.3%) and was thereby the only retail trade subsector with a rate above the non-financial business economy average. Most of the remaining retail subsectors recorded gross operating rates above the distributive trade average (5.1%), the exceptions being retail sales in non-specialised stores (4.1%) and the retail sale of automotive fuel in specialised stores (3.3%).

Country analysis

Retail trade is, by definition, a household-oriented service activity and retail trade enterprises often serve a local market. As such, there is relatively little specialisation in the activity as a whole and so it is unsurprising that the five Member States with the largest populations also contributed the most to EU-27 totals: Germany (21.7% of EU-27 value added), France (16.0%), the United Kingdom (15.9%), Spain (10.1%), Italy (9.6%). In relative terms, the most specialised Member State was Cyprus where 10.5% of non-financial business economy value added in 2009 resulted from retail trade activities. Other Member States that were relatively specialised in retail trade were Portugal and Spain, as the retail trade sector contributed 9.0% of non-financial business economy value added and Latvia where the share was 8.8%. The least specialised Member States, in value added terms, were the Czech Republic and Hungary, where the retail trade share of non-financial business economy value added was 5.6%; in Norway the share was lower still, at 4.8%.

Two Member States recorded wage-adjusted labour productivity ratios below 100% for the retail trade sector in 2009, namely Lithuania (91.0%) and Italy (81.6%), while all Member States, except for Slovenia, recorded wage-adjusted labour productivity ratios that were below their average ratios for the non-financial business economy. The gross operating rate for retail trade was also systematically lower than the average rate for the non-financial business economy in all Member States, ranging from 0.6% in Lithuania to 7.7% in Germany.

Focus on retail trade turnover specialisations

Due to the specific nature of retail trade, namely selling goods without transformation to final consumers, an analysis of turnover is of particular interest.

Specialised in-store retailing (Groups 47.2 to 47.7) generated just over half (53.4%) of retail trade turnover in 2009 in the EU-27, while non-specialised in-store retailing (Group 47.1) generated 42.0% of the total; retailing not in stores (Groups 47.8 and 47.9) accounted for the remainder. While retail trade as a whole is not an activity with strong specialisations between Member States, an analysis of turnover for these three regroupings does indicate a certain specialisation in different retailing formats between Member States. The turnover share in 2009 of specialised in-store retailing was highest in Sweden (59.7%), Belgium (also 59.7%), Spain (60.0%), Portugal (61.3%), the Netherlands (61.4%), Austria (63.8%) and Bulgaria (69.0%) and lowest in Slovakia (43.4%). In contrast, the turnover share of non-specialised retailing was highest in Estonia (48.1%), the United Kingdom (49.7%), Slovakia (51.6%) and Finland (53.4%) and lowest in Luxembourg (18.1%); it was higher still in Croatia (55.2%). Retail trading not in stores was highest in Germany and the Netherlands where it was over 6.0% of retail trade turnover, but it was less just 1.3% in Ireland.

At a more detailed level, it is possible to analyse in-store retailing of food, beverages and tobacco, comparing on one hand specialised retailers of these products and on the other hand non-specialised retailers with food, beverages and tobacco predominating (Class 47.11). For the EU-27 as a whole, a 12.8% share of the combined retail sales of these two activities was undertaken in specialised food, beverages and tobacco retail stores with the remainder in unspecialised stores with food, beverages and tobacco predominating. Among the Member States, the proportion of sales of these products in specialised stores rose to 27.3% in Poland and 25.6% in Spain, while it was as low as 5.3% in Estonia, 4.2% in Slovenia, 3.9% in Latvia and 1.9% in Lithuania.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the retail trade sector in the EU, as covered by NACE Rev.2 Division 47. This division includes the resale (sale without transformation) of new and used goods mainly to the general public for personal or household consumption or use. The sale is done in shops, department stores, from stalls, mail-order houses, or by door-to-door sales persons, hawkers, consumer cooperatives and so on.

Retail trade is classified first by type of outlet – distinguishing in-store retail trade from retail trade not in stores. Retail trade in stores is divided between non-specialised retail sale (for example, supermarkets or department stores) and specialised retail sale. These are then further subdivided with a distinction for non-specialised in-store retailing between stores with food, beverages or tobacco dominating and others, and a more detailed subdivision of specialised retail trade in stores based on the range of products sold. Retail sale not in stores is subdivided according to different forms of trade rather than the types of products sold. This division also includes retail sales by commission agents and activities of retail auctioning houses.

Handling that is customary in trade does not affect the basic character of the merchandise and may include, for example, sorting, separating, mixing and packaging.

This NACE division is composed of nine groups:

- retail sale in non-specialised stores (Group 47.1);
- retail sale of food, beverages and tobacco in specialised stores (Group 47.2);
- retail sale of automotive fuel in specialised stores (Group 47.3);

- retail sale of ICT equipment in specialised stores (Group47.4);
- retail sale of other household equipment in specialised stores (Group47.5);
- retail sale of cultural and recreation goods in specialised stores (Group47.6);
- retail sale of other goods in specialised stores (Group47.7);
- retail sale via stalls and markets (Group47.8);
- retail trade not in stores, stalls or markets (Group47.9).

The goods sold in this division are limited to goods usually referred to as consumer goods or retail goods. Therefore, goods not normally entering the retail trade sector, such as intermediate goods and industrial machinery are excluded. This division also excludes the sale of farmers' products by farmers (crop and animal production, hunting and related service activities, Division01), the combined manufacture and sale of goods which is generally classified as a manufacturing activity (Divisions10 to 32), the retail sale of motor vehicles, motorcycles and their parts and accessories (classified as part of the [motor trades](#) sector, Division45), the sale of food and drinks for consumption on the premises and sale of takeaway food (included as part of [food and beverage service activities](#) , Division56), or the renting of personal and household goods to the general public (which is part of the [renting and leasing of goods](#) , Division77).

Notes

Road and other land transport statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers road and other land transport statistics, corresponding to NACE Group 60.2, which is part of the [transport and storage](#) sector. The activities covered in this article are:

- road freight transport;
- urban and suburban passenger transport by bus, coach, tram, trolleybus, underground or elevated railway;
- inter-city land passenger transport (other than railways);
- taxi operations and charters.

This definition includes a diverse number of enterprises, ranging from independent lorry or taxi drivers to large national or metropolitan public transport [enterprises](#).

	Enterprises (thousand)	Turnover (EUR million)	Value added (EUR million)	Persons employed (thousand)	Share in total (%)	
					Value added	Persons employed
Road and other land transport (2)	900.0	370 000	150 000	4 616.0	100.0	100.0
Passenger land transport other than railways (3)	329.8	91 000	50 834	1 863.3	36.7	40.4
Freight transport by road	600.0	280 000	100 000	2 800.0	66.7	59.6

Table 4: Road and other land transport (NACE Group 60.2). Expenditure, productivity and profitability, EU-27, 2006 (1)

Main statistical findings

Structural profile

An estimated 900.0 thousand enterprises were registered in the EU-27's road and other land transport (NACE Group 60.2) sector which employed about 4.6 million persons in 2005. As such, the road and other land transport sector supplied just over half (52.9%) of the workforce in transport services (NACE Divisions 60 to

63). The proportion of paid employees in the total number of persons employed (which also includes working proprietors and unpaid family workers) was 80.7% in the EU-27 road and other land transport services sector in 2005, the only transport services activity where it was below the [non-financial business economy](#) average. This share was just below four fifths (79.4%) in the road freight transport subsector (NACE Class 60.24).

The EU-27's road and other land transport sector generated [value added](#) of EUR 150 billion in 2006 from [turnover](#) valued at EUR 370 billion. As such, road and other land transport accounted for close to two fifths (37.5%) of all value added generated by transport services in 2006. Within road and other land transport services the largest activity was the road freight transport (NACE Class 60.24) subsector. This subsector accounted for around two thirds of the value added created by the EU-27's road and other land transport sector in 2006 and occupied around three fifths of the workforce; other passenger land transport activities (NACE Classes 60.21 to 60.23) made up the remainder of the sector.

The relative importance of the road freight transport subsector on the one hand and other passenger land transport on the other differed considerably between the Member States¹²⁷: the share of road freight (in value added terms) rose to above 80% of the total in Estonia and Slovenia, while the other passenger land transport subsector generated more than half of sectoral value added in Greece and Cyprus (2005) – it should be noted that Cyprus has no rail network as an alternative form of inland passenger transport, and many residents and tourists therefore use other forms of public transport (notably buses, coaches, minibuses and taxis).

Unsurprisingly, the larger Member States contributed the greatest shares of EU-27 value added in this sector. The United Kingdom, France and Germany each accounted for around 15% of EU-27 value added in 2006. However, an analysis based on relative specialisation highlights the importance of the road and other land transport sector in several other Member States¹²⁸. For example, this activity contributed 5.8% of non-financial business economy value added in Lithuania, and over 3.5% in Latvia, Finland, Luxembourg, Spain, Slovenia and Greece. In contrast, the road and other land transport sector was notably smaller in relative terms in Cyprus (2005), Slovakia and Germany where it accounted for less than 2.0% of the value added created within the non-financial business economy.

Transport of goods and passengers

When analysing statistics on land transport equipment and traffic volumes it is important to bear in mind that this includes own account transport as well as transport services marketed to clients (for hire and reward). The growth in the stock of road transport vehicles (buses, coaches and road freight vehicles) between 1995 and 2006 for the EU-27 shows that road freight vehicles, in particular, experienced very strong growth whereas for buses and coaches the growth was more subdued, with the stock of such vehicles falling in 2004 and 2005, before stabilising in 2006. The volume of passenger transport by trams and metros increased significantly faster since 1995 than for buses and coaches, but both of these were outstripped by the growth in road freight which averaged an increase of 3.5% per year between 1995 and 2006.

Information relating to the development of road freight transport in the Member States is available for a shorter period, between 2000 and 2006. Only Belgium, Denmark, Cyprus and Finland witnessed a fall in road freight transport volumes during this period. The strongest growth was recorded in Romania, where the volume of road haulage increased four-fold, and it more than doubled in Lithuania, Slovenia, Latvia and Bulgaria.

Expenditure and productivity

Gross [tangible investment](#) in the EU-27's road and other land transport sector was around EUR 31.9 billion in 2005, resulting in an [investment rate](#) of 22.5%, lower than the transport services average but above the non-financial business economy average.

An analysis of [operating expenditure](#) shows a significant difference between the two subsectors, with personnel costs accounting for around one quarter of the total for road freight transport, compared to more than two fifths (44.4%) for other passenger land transport.

¹²⁷Cyprus and Poland, 2005; Bulgaria, Ireland and Malta, not available.

¹²⁸Cyprus, Poland and Romania, 2005; Bulgaria, Ireland, Malta and the Netherlands, not available.

The road and other land transport sector is characterised by a relatively low apparent [labour productivity](#) : in 2005, this was EUR 30.7 thousand per person employed in the EU-27, well below the transport services average of EUR 43.6 thousand. Average [personnel costs](#) were also low at EUR 26.1 thousand per employee in the road freight transport subsector in 2006, and EUR 26.7 thousand per employee for the other passenger land transport subsector. Despite the low average personnel costs the [wage-adjusted labour productivity ratio](#) was also relatively low, 120.1% for the road and other land transport sector in 2005, among the lowest of the transport services activities. Greece (78.9%) and Cyprus (56.5%, 2005) recorded wage-adjusted labour productivity ratios below 100% indicating that average personnel costs were higher than apparent labour productivity.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include Eurostat, ITF, IUPT, national statistics, estimates and the United Nations Economic Commission for Europe, in EU energy and transport in figures statistical pocketbook 2007/2008, European Commission, Directorate-General for Energy and Transport

Context

The transport and storage sector focuses on transport services provided to clients for hire and reward. When analysing transport traffic volumes (for example, tonnes of freight) as presented in this article, it is important to bear in mind that these include own account transport as well as transport services for hire and reward. This is particularly important in road transport where, for example, a manufacturer might collect materials or deliver own [output](#) , rather than contracting a transport service enterprise to do this. Equally, the use of own vehicles (typically passenger cars) accounts for a very large part of passenger transport. Such own account transport does not contribute towards the statistics on the transport services sector.

EU transport policy is based upon the [2001 White paper 'European transport policy for 2010: time to decide'](#) and the 2006 mid-term review in the European Commission's communication ([COM\(2006\) 314](#)) 'Keep Europe moving – sustainable mobility for our continent'. In 2007 the European Commission adopted a communication ([COM\(2007\) 606](#)) on 'Keeping freight moving', to make rail freight more competitive, facilitate modernisation of ports, and review progress in the development of sea shipping.

Environmental issues remain of great importance to this sector, as transport is a major source of emissions and noise. In 2008 the European Commission put forward a package of measures related to road and rail transport referred to as 'Greening Transport'. This included a communication ([COM\(2008\) 433](#)) summarising the packages and initiatives planned for 2009, a strategy to internalise the cost of transport externalities, a proposal for a Directive on road tolls for lorries, and a communication on rail noise. The overall thrust of the package is to try to move towards more sustainable transport.

Over a long period road freight transporters have expanded beyond simple transport services, to provide other supporting activities, notably logistics and warehousing, competing with specialists in these activities as well as wholesalers who have also extended the range of their operations into transport and supporting activities. Road transport has been one of the main areas of growth in the transport services sector as it benefited from increased demand for mobility and flexibility from private individuals and enterprises alike. In May 2007 the European Commission adopted three proposals ([COM\(2007\) 263](#)), ([COM\(2007\) 264](#)) and ([COM\(2007\) 265](#)) aimed at modernising the rules governing road transport operators and access to the road transport market. The proposals aim to reduce distortions of competition and improve transport operators' compliance with the provisions of social legislation and road safety rules.

In July 2008, the European Commission adopted a proposal ([COM\(2008\) 436](#)) to reform the legislation on road charges for heavy goods vehicles, the so-called 'Eurovignette'. The proposal is intended to enable Member States to reduce environmental damage and congestion through more efficient and environmentally-targeted road tolls for lorries.

A [Regulation](#) on public passenger transport services by rail and by road was adopted in October 2007. Its purpose is to define the conditions under which public service operators providing services of general interest may be compensated for costs incurred, and/or may be granted exclusive rights in return for the discharge of public service obligations.

In September 2007 the European Commission published a Green paper on urban transport ([COM\(2007\) 551](#)), to look, among others, at the questions of congestion and pollution linked to urban transport.

Notes

Rubber and plastics production statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article introduces a [set of statistical articles](#) which analyse the structure, development and characteristics of the economic activities in the rubber and plastics sector in the [European Union \(EU\)](#) . This sector covers [NACE Rev 1.1 Subsection DH](#), and its activities are treated in more depth in two further articles:

- [Rubber production](#) , corresponding with NACE Group 25.1;
- [Plastics production](#) , corresponding with NACE Group 25.2.

	Enterprises		Turnover		Value added		Persons employed

Table 6: Manufacture of rubber and plastic products (NACE Division 25). Main indicators, 2006 (1)

There were 64.9 thousand enterprises throughout the EU-27 for whom the manufacture of rubber and plastics (NACE Subsection DH) was their main activity in 2006, and they employed about 1.9 million persons. These enterprises generated a turnover of EUR 274.6 billion in 2006, of which EUR 78.4 billion or about one quarter (28.5%) was added value. As a share of the value added generated by the whole of the non-financial business economy (NACE Sections C to I and K), the rubber and plastics sector contributed 1.4%.

In terms of enterprise numbers, size of workforce and value added generated, the manufacture of plastic products (NACE Group 25.2) subsector was much larger than the manufacture of rubber products subsector (NACE Group 25.1). The plastic products manufacturing subsector comprised 57.2 thousand enterprises in 2006, with a workforce of about 1.4 million persons, and generated EUR 60.0 billion of value added. This contrasted with a rubber products manufacturing sector of 7.7 thousand enterprises, with a workforce of about 0.4 million persons, which generated EUR 18.0 billion of value added.

The rubber and plastics manufacturing sector in Germany generated just over one quarter (27.4%) of the value added generated within the EU-27 in 2006. In these terms, the German rubber and plastics sector was almost twice the size of that in France (14.6%), which was the second largest producer within the EU. Although the contribution of the rubber and plastics sector to non-financial business economy value added in Germany

was slightly higher than the EU-27

average (1.9% compared with 1.4%), Germany was far from being the most specialised Member State. In these relative terms, Luxembourg was the most specialised country, as rubber and plastics contributed 3.2% of the added value of the non-financial business economy; this was followed closely by the Czech Republic and Slovenia.

These three Member States were also the most specialised in terms of the relative importance of the rubber and plastics workforce and its contribution to the total number of persons employed within the non-financial business economy. At a regional level (the NUTS 2 level of detail shown in the map), the highest proportion (7.8%) of the non-financial business economy workforce engaged in rubber and plastics manufacturing was in Auvergne (France). There were a number of other regions in France, as well as in Germany, the Czech Republic and Poland, together with Luxembourg (that is treated as a single region at the level of detail shown), where there was also relatively strong regional specialisation in rubber and plastics manufacturing.

There was a fairly steady upward development in the [production index](#) of the EU-27's rubber and plastic products manufacturing activity during the ten years through to 2007, albeit it with a couple of years of stagnation in 2001 and 2002. This was an almost exact mirror of the annual development for the whole of the industrial economy (NACE Sections C to E). Over the ten year period considered, the average rate of growth for rubber and plastic products output was 2.4% per year. There was also little difference in the development of [output](#) between rubber products manufacturing on the one hand and plastic products manufacturing on the other, except that the output of rubber products manufacturing fell rather than stagnated in 2001 and 2002.

In a similar vein, there was also little difference in the evolution of domestic output prices for rubber products and plastic products during the same ten year period; the average rate of increase in output prices for rubber and plastic products across the EU-27 was 1.0% per year, reflecting relatively small price declines through until 2000 followed by a gradual upturn in prices until 2007. This overall pattern of price development was similar to that noted for the whole of total industry, although the upturn in prices after 2000 was less strong from rubber and plastics.

However, there was a much greater distinction in terms of [employment](#). The EU-27 rubber and plastics manufacturing sector was the only manufacturing (NACE Section D) subsection in which there was employment growth in the ten years through to 2007, rising at an average rate of 0.7% per year. This contrasted with relatively persistent employment declines (at an average 1.2% per year) for total industry.

Unlike many other industrial sectors, and more in line with the non-financial business economy as a whole, a majority (57.4%) of both the value added generated by the rubber and plastics manufacturing sector in the EU-27 and its workforce (64.1%) came from [small and medium-sized enterprises](#) (those employing less than 250 persons). However, within small and medium-sized enterprises, [micro-enterprises](#) (employing less than 10 people) provided a particularly low proportion of value added (4.8%) and the workforce (7.8%) – the relative difference being made up by [medium-sized enterprises](#) (those employing between 50 and 249 persons). Although the apparent [labour productivity](#) of rubber and plastics manufacturing enterprises rose through the size groups, there were also diminishing productivity gains. This contrasted with industry as a whole, where productivity gains accelerated through the size classes.

The size structure of the rubber and plastics manufacturing sector was somewhat atypical in Germany and France (the two countries with the highest levels of output), as well as the Czech Republic (one of the most specialised Member States) in 2006, as all three of these Member States reported that [large enterprises](#) (employing 250 or more persons) generated a majority of sectoral value added in 2006.

Employment characteristics

A clear majority (71.5%) of the rubber and plastics manufacturing sector's workforce was male; this figure was above the average (64.9%) for the whole of the EU-27 non-financial business economy in 2007. There was also a more notable prevalence of full-time work in the rubber and plastics manufacturing sector (93.9% compared with 85.7% for the non-financial business economy). In contrast, the age structure was fairly similar, albeit with a slightly higher majority (56.5% compared with 53.7%) of workers in the rubber and plastics manufacturing sector aged between 30 and 49 years old.

These employment characteristics for the EU-27 as a whole were also observed in most of the Member States.

The proportion of men in the workforce was as much as 10 to 20 percentage points higher than the non-financial business economy average in the Netherlands, Spain, Belgium, the United Kingdom, Latvia, Ireland, Cyprus and Luxembourg. However, it was lower than the non-financial business economy average in Hungary and particularly in Estonia, which was the only Member State where women formed a majority (51.3%) of the rubber and plastics manufacturing sector's workforce.

As with many other industrial activities in Denmark and the Netherlands, the proportion of young workers under the age of 30 in the rubber and plastics manufacturing sector was well below (about ten percentage points less) the share of this age group across their respective non-financial business economies. In contrast, there were relatively high proportions of young persons working within rubber and plastics manufacturing in Bulgaria and particularly Poland. Indeed, in the latter, young workers represented a little over a third (36.0%) of the workforce in this sector, the highest proportion among the Member States.

Expenditure, productivity and profitability

Just under four fifths (79.2%) of operating expenditure in the EU-27's rubber and plastics manufacturing sector went on purchases of goods and services in 2006, a slightly lower proportion than the average (83.9%) across the whole of the non-financial business economy.

Tangible investment was EUR 11.8 billion in 2006, representing 1.1% of total investment across the non-financial business economy of the EU-27. This was a lower share than the rubber and plastics manufacturing sector's contribution to total value added, resulting in an **investment rate** (15.1%) that was lower than the non-financial business economy average (18.4%). Among the Member States, investment rates in the rubber and plastics manufacturing sector were between 10 and 15 percentage points lower than average rates for the respective non-financial business economies of Belgium, Portugal, Sweden, Denmark, Slovenia, Slovakia and Lithuania. In contrast, rates were considerably higher in Poland (33.3% compared with 19.5% in 2005) and, in particular, Bulgaria (84.0% compared with 56.7%).

The average value added generated per person employed in the EU-27's rubber and plastics manufacturing sector was EUR 44.8 thousand in 2006, about EUR 1.3 thousand more than the non-financial business economy average. **Personnel costs** per employee averaged EUR 30.9 thousand in the EU-27 in 2006, which was about EUR 2.1 thousand higher than for the whole of the non-financial business economy. In wage adjusted terms, therefore, the labour productivity of the EU-27's rubber and plastics manufacturing sector (145.1%) was a little lower than the non-financial business economy average (151.1%) in 2006. This was also the case for the wage adjusted productivity ratios of the rubber products subsector (143.7%) and the plastic products subsector (144.7%), between which there was also relatively little difference in apparent labour productivity levels nor average personnel costs.

Among Member States, however, there were stark contrasts between the wage adjusted labour productivity ratios. In this respect, neighbouring Latvia and Lithuania provided the two greatest extremes: on the one hand, the ratio for the rubber and plastics manufacturing sector in Latvia was significantly lower than its non-financial business economy average (195.4% compared with 255.7%); while, in Lithuania, on the other, it was significantly higher (254.9% compared with 177.4%).

The gross operating rate of the EU-27's rubber and plastics manufacturing sector was 9.6% in 2006, slightly lower than the average (10.8%) across the EU-27's non-financial business economy. Again, there was relatively little difference in the corresponding rates between the two subsectors.

External trade

About three quarters (76.9%) of the Member States' total **exports** of rubber and plastic products (CPA Sub-section DH) in 2007 were destined for other Member States, which represented a notably higher share than the average (67.6%) for all industrial goods (CPA Sections C to E).

Exports of rubber and plastic products from the EU-27 to non-member countries (**extra-EU trade**) were valued at EUR 27.1 billion in 2007, whilst imports were valued at EUR 24.3 billion. The resulting net trade surplus of EUR 2.8 billion in 2007 represented a narrowing of the surplus (compared with 2006) after a number of years of the surplus growing. Whereas the EU-27 **trade surplus** for plastic products (CPA Group 25.2) continued to

widen to EUR 4.0 billion in 2007, the [trade deficit](#) for rubber products (CPA Group 25.1) increased considerably to EUR 1.2 billion, driven by a rapid increase (21.0%) in the value of imports when compared with their level in 2006.

The value of EU-27 exports of rubber and plastic products represented 2.3% of all industrial exports in 2007. The principal export markets for the EU-27's rubber and plastic products were the United States, Switzerland and Russia. The position of the United States as the principal export market was partially eroded between 2006 and 2007, however, as a result of a falling level of EU-27 exports to this country at the same time as the value of the total export market for these products grew.

There was relatively little difference in the relative shares of the EU-27's three main export partners for plastic products, whereas for rubber products the United States continued to account for around one fifth of the EU-27's exports in 2007, which was slightly more than twice the proportion accounted for by Russia, the second highest share.

The value of imports of rubber products from China and Japan were similar, together accounting for a little less than one third (31.9%) of all such imports to the EU-27 in 2007, although the year on year growth in the value of imports from China in 2007 was twice as strong as that for Japan (43.6% compared with 17.9%).

Imports of plastic products from China accounted for a little less than one third (30.6%) of EU-27 imports in 2007, which was slightly more than the combined value of imports from the United States and Switzerland (the second and third most important origin of EU-27 imports for plastic products).

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include [short-term statistics \(STS\)](#) , the [Labour force survey \(LFS\)](#) and the [COMEXT](#) database for external trade.

Context

Recent legislation within this area has focused on environmental issues, with a key development being the adoption of the revised Waste Framework Directive ([2008/98](#)) of the [European Parliament](#) and of the [Council](#) in November 2008. This sets out the basic concepts and definitions related to waste management and lays down waste management principles such as the 'polluter pays principle' or the 'waste hierarchy'. With regard to the rubber and plastics manufacturing sector, the Directive obliges Member States to take measures to promote high quality recycling and, to this end, set up separate collections of waste. By 2020, the recycling of waste materials such as plastics, among others, from households should be increased to a minimum of 50% by weight. End-of-waste criteria that provide a high level of environmental protection and an environmental and economic benefit should be laid down for tyres.

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). The present article covers rubber production, corresponding to [NACE Rev 1.1 Group 25.1](#), which is part of the [rubber and plastics](#) sector. The activities covered in this article are:

- the manufacture of rubber tyres and tubes;
- the retreading and rebuilding of rubber tyres;
- the manufacture of other rubber products.

	Enterprises (thousand)	Turnover (EUR million)	Value added (EUR million)	Persons employed (thousand)	Share in total (%)	
					Value added	Persons employed

Table 4: Manufacture of rubber products (NACE Group 25.1). Expenditure, productivity and profitability, EU-27, 2006

According to the [International Rubber Study Group](#), the EU is self-sufficient in synthetic rubber, producing 2.8 million tonnes of synthetic rubber in 2007 (corresponding to 20.5% of world production) but consuming 2.6 million tonnes. In contrast, the EU produces no natural rubber but consumed 1.4 million tonnes.

Structural profile

Rubber products manufacturing was the principal activity of a little over 7.7 thousand [enterprises](#) throughout the [EU-27](#) in 2006. These enterprises employed an estimated 368.0 thousand persons, about one fifth (21.1%) of the rubber and plastics manufacturing workforce. The [turnover](#) generated by the rubber products manufacturing sector was EUR 64.9 billion in 2006, of which EUR 18.0 billion was [value added](#), which corresponded to a little less than one quarter (23.0%) of the value added generated by the combined activities of rubber and plastics manufacturing in the EU-27.

The manufacture of other rubber products (NACE Class 25.13), such as tubes, pipes, hoses, seals and other articles of vulcanised rubber, accounted for one half (50.9%) of the EU-27's added value within rubber products manufacturing in 2006. The value added created by the rubber tyres and tubes manufacturing subsector (NACE Class 25.11) accounted for most of the remainder (46.4%), leaving a very small retreading and rebuilding of rubber tyres subsector (NACE Class 25.12).

The rubber products manufacturing sector in Germany was larger than that of any other Member State in terms of the value added generated, contributing one quarter (25.6%) of the EU-27 total in 2006. A further one fifth (19.3%) of EU-27 value added generated in this sector came from activities in France. In terms of the relative contribution of the rubber products manufacturing sector to the value added generated in each Member State's [non-financial business economy](#), by far the most specialised Member State was Luxembourg, where these activities contributed six times the EU-27 average. The Czech Republic, Slovakia and Slovenia were also relatively specialised in the manufacture of rubber products, with these activities contributing between two and a half and three times the EU-27 average.

The EU-27 index of production for rubber products manufacturing followed an upward trend during the period between 1997 and 2007, with average growth of 2.4% per year, despite a contraction in output in 2001. The development of the [output](#) for other rubber products followed closely the evolution for the whole of rubber products. In contrast, the production index of rubber tyres and tubes manufacturing was little different in 2007 from the level of 2000, with much slower growth after the relative trough recorded in 2001; over the ten year period through to 2007, output grew by an average 0.2% per year.

Expenditure and profitability

About one fifth (22.0%) of [tangible investment](#) across all rubber and plastics manufacturing activities in the EU-27 was spent on rubber products manufacturing in 2006. This represented a slightly lower share than the corresponding ratio for value added, resulting in an [investment rate](#) for rubber products manufacturing (14.4%) that was somewhat below the average (15.1%) for rubber and plastics manufacturing.

The operating cost structure of the EU-27's rubber manufacturing sector was very similar to that for rubber and plastics manufacturing as a whole, as about one fifth (20.6%) of operating expenditure was accounted for by personnel costs, leaving the majority spent on purchases of goods and services.

Each person employed in the EU-27's rubber products manufacturing sector generated an average of EUR 48.9 thousand of value added in 2006, which more than covered average personnel costs of EUR 34.0 thousand per employee. The resulting wage adjusted labour productivity ratio of 143.7% was very similar to the average for the whole of the rubber and plastics manufacturing sector.

In Denmark, the average value added generated per worker within the rubber products manufacturing sector in 2006 was insufficient to cover average [personnel costs](#) (being almost 20% less). In Denmark, Bulgaria and Lithuania, the wage adjusted labour productivity ratio of the rubber products manufacturing sector was between 70 and 100 percentage points lower than the average for rubber and plastics manufacturing as a whole. In contrast, wage adjusted labour productivity was relatively high in the Czech Republic (60 percentage points above the rubber and plastics manufacturing average).

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include the [PRODCOM](#) statistics on the production of manufactured goods.

Context

Recent legislation within this area has focused on environmental issues, with a key development being the adoption of the revised [Waste Framework Directive](#) of the [European Parliament](#) and of the [Council](#) in November 2008. This sets out the basic concepts and definitions related to waste management and lays down waste management principles such as the 'polluter pays principle' or the 'waste hierarchy'. With regard to the rubber and plastics manufacturing sector, the Directive obliges Member States to take measures to promote high quality recycling and, to this end, set up separate collections of waste. By 2020, the recycling of waste materials such as plastics, among others, from households should be increased to a minimum of 50% by weight. End-of-waste criteria that provide a high level of environmental protection and an environmental and economic benefit should be laid down for tyres.

Following legislation regarding retreaded tyres and bans on shredded tyres in landfill, more recent legislative proposals have focussed on the impact that tyres can have on better fuel efficiency. A proposal for a regulation of the European Parliament and of the Council ([COM\(2008\) 316](#)) regarding type-approval requirements for the general safety of motor vehicles was put forward in May 2008, which in part looks to enhance the environmental performance of vehicles by reducing the amount of road noise and vehicle CO2 emissions from tyres. A complementary proposal for a directive of the European Parliament and of the Council ([COM\(2008\) 779](#)) on the labelling of tyres with respect to fuel efficiency and other essential parameters was put forward in November 2008, which could enable consumers to readily identify energy-efficient and better performing tyres.

Table 4b: Key indicators, scientific research and development (NACEDivision72), 2009 - Source: Eurostat (sbs_na_1a_se_r2)

Main statistical findings

Structural profile

There were 45 thousand enterprises operating with scientific research and development services (Division72) as their main activity in the EU-27 in 2009; note that this includes only enterprises that have the provision of research and development services as their main activity and does not reflect the research and development function of enterprises in other activities. Together these specialist research and development enterprises employed 483 thousand persons, approximately 0.4% of the total number of persons employed in the non-financial business economy (Sections B to J and L to N and Division95) and 4.4% of the workforce for professional, scientific and technical activities (Section M). They generated EUR22218 million of value added which was also approximately 0.4% of the non-financial business economy total and 4.3% of the professional, scientific and technical activities

total.

The [apparent labour productivity](#) of the EU-27's scientific research and development services sector in 2009 was EUR46 thousand per person employed, above the non-financial business economy average (EUR41.6 thousand per person employed) but slightly below the professional, scientific and technical activities average (EUR47 thousand per person employed). [Average personnel costs](#) within the EU-27's scientific research and development services sector were EUR48.2 thousand per employee, reflecting the relatively high level of qualifications held by many persons within the workforce. However, this level of average personnel costs was higher than the apparent labour productivity per person employed. This was the second highest level of average personnel costs among the seven NACE divisions that make up the professional, scientific and technical activities (where the average was EUR40.5 thousand per employee) and around three fifths higher than the non-financial business economy average (EUR30.0 thousand per employee).

As average personnel costs exceeded apparent labour productivity the [wage-adjusted labour productivity ratio](#) for the EU-27's scientific research and development services sector was below 100% in 2009: standing at 95.6% this sector's wage-adjusted labour productivity ratio was the third lowest among all of the NACE divisions within the non-financial business economy, higher only than the ratios observed for the [repair of computers and personal and household goods](#) (Division95) and [air transport](#) (Division51). Equally, the [gross operating rate](#) (the relation between the [gross operating surplus](#) and [turnover](#)) of the EU-27's scientific research and development services sector was very low, at 0.9% in 2009. This was the second lowest rate among all of the non-financial business economy NACE divisions in 2009, higher only than for air transport.

Sectoral analysis

Scientific research and development services can be split between those services concerning natural sciences and engineering (Group72.1) and those concerning social sciences and humanities (Group72.2). In the EU-27 the research and experimental development on natural sciences and engineering subsector was considerably larger, with 72.5% of the scientific research and development services enterprise population and more than 90% of the sectoral workforce and sectoral value added.

Country analysis

The scientific research and development services sector was the only one of the seven sectors within professional, scientific and technical activities where Germany made the largest contribution to EU-27 value added: the German share of almost one third (32.2%) was followed by an 18.1% share for the United Kingdom and a share of 14.4% for France.

Among the Member States, Denmark, the Netherlands, Germany and Slovenia were the most specialised in scientific research and development services sector in 2009, as 0.6% of their non-financial business economy value added was generated in the scientific research and development services sector; there was a higher degree of specialisation recorded in Switzerland (1.3%). An analysis of specialisation based on employment shows a similar picture, with the notable difference that Sweden and the United Kingdom were the second and third most specialised Member States behind the Netherlands.

The exceptionally low wage-adjusted labour productivity ratio recorded for the EU-27's scientific research and development services sector in 2009 was reflected in low wage-adjusted labour productivity ratios for most Member States, with six recording rates below 100% – including, a negative rate for Sweden, reflecting its negative value added in this sector. Nevertheless, wage-adjusted labour productivity ratios close to 200% were observed for Latvia and Bulgaria in 2009, while the Portuguese ratio reached 229.9%: these three Member States were the only ones to record wage-adjusted labour productivity ratios for the scientific research and development services sector that was above their non-financial business economy average.

For the gross operating rate the performance of the Member States in the scientific research and development services sector was even more varied in 2009. Three Member States – Sweden, Estonia and the United Kingdom – recorded negative profitability (using this measure); as did Norway. In contrast, ten Member States recorded a gross operating rate for the scientific research and development services sector that was above their non-financial business economy average; as did Switzerland and Croatia. The highest gross operating rates in

the scientific research and development services sector in 2009, all in excess of 25%, were recorded in Portugal, Bulgaria and Latvia.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the scientific research and development services sector in the EU, as covered by NACE Rev.2 Division72. This division includes the activities of various types of research and development. Basic research is experimental or theoretical work undertaken primarily to acquire new knowledge of the underlying foundations of phenomena and observable facts, without particular application or use in view. Applied research is original investigation undertaken in order to acquire new knowledge, directed primarily towards a specific, practical aim or objective. Experimental development is systematic work, drawing on existing knowledge gained from research and/or practical experience, directed to producing new materials, products and devices, to installing new processes, systems and services, and to improving substantially those already produced or installed. These can be divided between the different subject areas, for example, biotechnology, natural sciences, engineering and technology, medical sciences, agricultural sciences, social sciences and humanities.

This NACE division is composed of two groups:

- research and experimental development on natural sciences and engineering (Group72.1);
- research and experimental development on social sciences and humanities (Group72.2).

The information that is presented in this article does not include market research activities, which are classified within NACE as part of the [advertising and market research](#) sector (Division73).

Second-hand goods in-store retail trade statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers second-hand goods in-store retail trade, corresponding to NACE Group 52.5, which is part of the [retail trade and repair](#) sector. The retailing of second-hand goods deals by definition with the sale of semi-durable and durable items, and includes shops selling:

- antiques;
- second-hand books;
- second-hand clothes.

This article excludes the [retail sale of second-hand motor vehicles](#).

Table 1: Retail sale of second-hand goods in stores (NACE Group 52.5). Structural profile: ranking of top five Member States in terms of value added and persons employed, 2006

Main statistical findings

Turnover was EUR 8.1 billion in the [EU-27](#)'s sector of second-hand goods retailing in stores (NACE Group 52.5), from which EUR 2.0 billion of **added value** was generated, the smallest level of **output** among the retail trade and repair sub-sectors. For each of these measures the relative weight of second-hand goods retailing in the retail trade and repair (NACE Division 52) total was 0.5% or below. Across the 65.7 thousand **enterprises** with second-hand goods retailing as their main activity, there were 120.4 thousand persons **employed** in the EU-27, therefore equating to 0.7% of the retail trade and repair workforce.

The United Kingdom alone accounted for 32.0% of the EU-27's turnover and 36.1% of value added in second-hand goods retailing in stores, while its share of the EU-27's workforce was just 16.6%. France was the second largest contributor in this sector in output terms, while Poland had the second largest workforce. Unsurprisingly, the United Kingdom was the most specialised Member State¹²⁹ in terms of the contribution of this sector to non-financial business economy value added, although this was still less than 0.1%.

Within the second-hand goods retailing in stores sector the apparent **labour productivity** was exceptionally low in the EU-27 in 2006, just EUR 16.9 thousand per person employed, the fourth lowest level recorded among all of the NACE groups within the [non-financial business economy](#) (with 2005 or 2006 data available). Apparent **personnel costs** were also low, EUR 14.6 thousand per employee, resulting in a **wage-adjusted labour productivity ratio** of just 115.1%, below the retail trade and repair average of 128.1%.

Approximately half of the Member States¹³⁰ recorded a wage-adjusted labour productivity ratio below 100% for their second-hand goods retailing in stores sector, indicating that average personnel costs were higher than

¹²⁹Bulgaria, Cyprus, Poland and Romania, 2005; Malta and the Netherlands, not available.

¹³⁰Bulgaria and Poland, 2005; Malta, not available.

the apparent labour productivity.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Context

Retailing is typically the final stage of distribution between producers and consumers. Since the development of the Internet, there has been an increasing use of commerce via the web. As such, there has been a gradual shift from traditional methods of purchasing from stores or markets to purchasing remotely. According to Eurostat's information society statistics, some 12% of the turnover of distributive trades (including motor trades (NACE Division 50) and wholesale trades (NACE Division 51), as well as retail trade and repair) enterprises with ten or more persons employed was derived from [e-commerce](#) in 2008. According to the same source, one quarter of the EU-27's population ordered or bought goods or services for private use through the Internet in 2008 (during the three months preceding the survey). Note that these figures refer to goods and services supplied to individuals by all sectors of the economy, not just enterprises that are specialised in retail sales.

In October 2008, the [European Commission](#) put forward a [proposal COM\(2008\) 614](#) for a Directive on consumer rights, to try to make purchases easier and safer, whether in-store or not. The proposal covers the provision of price information, protection against late delivery and non delivery, as well as setting out rights on issues such as cooling-off periods, returns, refunds, repairs and guarantees and unfair contract term.

Table 4b: Key indicators, security and investigation activities (NACE Division80), 2009 - Source: Eurostat (sbs_na_1a_se_r2)

Main statistical findings

Structural profile

There were around 50 thousand enterprises operating within the security and investigation services (Division80) sector in the EU-27 in 2009. They employed 1.38 million persons, which was equivalent to 1.0% of the total workforce within the non-financial business economy (Sections B to J and L to N and Division95) or slightly more than one in ten (11.5%) of those employed in administrative and support services (Section N). EU-27 security and investigation services enterprises generated EUR29035 million of value added which was 0.5% of the non-financial business economy total or 8.3% of the administrative and support services total.

The apparent labour productivity of the EU-27's security and investigation services sector in 2009 was EUR21 thousand of value added per person employed, which was almost half the non-financial business economy average (EUR41.6 thousand) and some EUR8 thousand below the administrative and support services average. As such, the security and investigation services sector recorded the fourth lowest level of apparent labour productivity among all of the NACE divisions that make-up the non-financial business economy.

Alongside this very low level of apparent labour productivity, average personnel costs within the EU-27's security and investigation services sector were also relatively low at EUR18.6 thousand per employee in 2009, some EUR11.4 thousand below the average for the non-financial business economy and EUR2.3 thousand lower than the average for administrative and support services. EU-27 average personnel costs for the security and investigation services sector were the fifth lowest across all of the NACE divisions within the non-financial business economy.

The wage-adjusted labour productivity ratio combines the two previous indicators and shows the extent to which value added per person employed covers average personnel costs per employee. With both of these indicators being very low they largely cancelled out a large part of the differences when compared to benchmark values such as those for the non-financial business economy. However, with apparent labour productivity being proportionally lower than average personnel costs this resulted in wage-adjusted labour productivity for the EU-27's security and investigation services sector of 113.4%, somewhat inferior to the non-financial business economy average (138.8%) or the administrative and support services average (139.1%).

The gross operating rate (the relation between the gross operating surplus and turnover) is one measure of operating profitability; it stood at 9.6% for the EU-27's security and investigation services sector in 2009, which was broadly in line with the non-financial business economy average (9.7%), but lower than the administrative and support services average (15.2%).

Sectoral analysis

Around seven in every ten enterprises within the EU-27's security and investigation services sector were classified as operating within the private security activities (Group80.1) subsector, while around one in six were in the security systems service activities subsector (Group80.2), leaving the residual engaged in investigation activities (Group80.3).

In terms of output and persons employed, the relative importance of private security activities was more pronounced, as this subsector accounted for 87.4% of sectoral value added and for 87.5% of the sectoral workforce. The majority of the remainder was accounted for by the security systems service activities subsector, with an 11.2% share of added value and a 10.7% share of the workforce. Investigation activities accounted for less than 2% of sectoral value added or employment.

The low apparent labour productivity figure for the whole of the security and investigation services sector was a pattern repeated across all three subsectors, as this ratio ranged from a high of EUR22 thousand of added value per person employed for the EU-27's security systems service activities subsector to a low of EUR17 thousand per person employed for investigation activities; the latter was the fifth lowest level of apparent productivity among any of the NACE groups that constitute the non-financial business economy.

Average personnel costs mirrored the pattern for apparent labour productivity insofar as they were consistently well below the non-financial business economy average for all three security and investigation services subsectors, while the lowest level of EU-27 average personnel costs was recorded for investigation activities (EUR12.8 thousand per employee in 2009); this latter figure was the second lowest level of average personnel costs per employee for any of the NACE groups that make-up the non-financial business economy.

All three security and investigation services subsectors also reported EU-27 wage-adjusted labour productivity ratios in 2009 that were below the non-financial business economy average of 138.8%. These ranged from 129.5% for investigation activities down to 112.1% for the largest subsector, private security activities.

There were wider differences between the three subsectors in relation to their gross operating rates. This lowest operating profitability rate (using this measure) was recorded for the EU-27's private security activities subsector, at 9.2% in 2009. This was also the only subsector where the gross operating rate was below the non-financial business economy average (9.7%). In contrast, operating profitability rose to 12.2% for security systems service activities and peaked at 18.6% (almost double the non-financial business economy average) for investigation activities.

Country analysis

The United Kingdom accounted for an 18.0% share of EU-27 value added within the security and investigation services sector in 2009. The United Kingdom also recorded the highest share of EU-27 added value for the private security activities subsector (19.7%), while France had the biggest share of the security systems service activities subsector (21.1%) and Germany for the investigation activities subsector (20.7%).

In relative terms, the value added generated by the security and investigation services sector in 2009 accounted for 1.2% of non-financial business economy added value in Estonia, the highest share among those Member States for which data are available; Bulgaria, Latvia and Romania all reported shares of at least 1.0%. At the other end of the range, the least specialised Member States in relation to the security and investigation services sector included Denmark, Cyprus and Austria, where this activity generated no more than 0.2% of value added within the whole of the non-financial business economy.

The United Kingdom was also the leading employer within the security and investigation services sector, as its workforce of 212.3 thousand persons was equivalent to almost one in six (15.4%) of the EU-27 total in 2009, followed by France (note that the data relate to employees and not persons employed), Germany and Poland; these three Member States each had a workforce of more than 140 thousand persons.

All of the Member States for which data are available in 2009 reported wage-adjusted labour productivity

ratios for security and investigation services that were above 100%. However, none of the Member States recorded wage-adjusted labour productivity ratios for the security and investigation services sector that were higher than their respective non-financial business economy averages. The highest wage-adjusted labour productivity ratios were recorded in Bulgaria (131.2%), the United Kingdom, Estonia and Latvia – the latter three countries all had ratios between 125.4% and 122.8%.

For the gross operating rate there was a wider range of values, with just under half of the Member States for which data are available reporting that they had a higher profitability rate for security and investigation services than they did for their respective non-financial business economies. This was most evident in Sweden where the gross operating rate for security and investigation services reached 15.2%, some 6.6 percentage points higher than the Swedish non-financial business economy average. The United Kingdom reported a higher gross operating rate (15.6%) but this figure was just 2.6 percentage points higher than the non-financial business economy average. In contrast, the lowest gross operating rate was recorded in France (3.0%), compared with a non-financial business economy average of 6.4%.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the security and investigation services sector in the EU, as covered by NACE Rev.2 Division80. It includes security-related services such as private security services, security systems services and investigation activities. Private security activities include the provision of guard and patrol services, protected pick-up, transit and delivery of valuable items (including money), bodyguard services and fingerprinting services. Security systems service activities include monitoring of electronic security alarm systems (such as burglar and fire alarms) including their installation and maintenance. Also included are installing, repairing, rebuilding, and adjusting mechanical or electronic locking devices, safes and security vaults in connection with later monitoring and remote monitoring. Investigation activities include investigation and detective services regardless of the type of client or purpose of investigation.

This NACE division is composed of three groups:

- private security activities (Group80.1);
- security systems service activities (Group80.2);
- investigation activities (Group80.3).

Public order and safety activities, which form part of public administration and defence; compulsory social security (Division84) are excluded, as are the installation or sale of security systems without later monitoring – which form part of [specialised construction activities](#) (Division43) and [retail trade](#) (Division47). Also excluded are services of security consultants, which form part of [other professional, scientific and technical activities](#) (Division74).

Table 5: Other business activities (NACE Division 74), 2006

Main statistical findings

Structural profile

The other business services sector (NACE Groups 74.6 to 74.8) created EUR 168.1 billion of **value added** in the EU in 2006 from total **turnover** of EUR 326.4 billion. These values represented 18.8% of the business services (NACE Divisions 72 and 74) value added and 18.5% of its turnover. This output was generated by just over 1.0 million **enterprises** employing 6.9 million persons, approximately one quarter (23.1%) and three tenths (31.0%) of the business services totals respectively. Among the three subsectors (NACE groups) covered by the other business services sector, miscellaneous business activities (NACE Group 74.8) was the largest in turnover and value added terms accounting for more than half of the sectoral total. However, industrial cleaning (NACE Group 74.7) had the largest workforce of the three subsectors covered, employing 3.1 million persons.

More than one quarter of the EU's value added in the other business services sector came from the United Kingdom (25.9%), which was also the second most specialised Member State in terms of this sector's share of **non-financial business economy** (NACE Sections C to I and K) value added after Luxembourg. Germany had the largest workforce in other business services. At a more detailed level, the United Kingdom was the largest Member State (in value added terms) in two of the subsectors, but was only fourth largest in industrial cleaning, where Germany, France and Italy were larger.

Expenditure and productivity

An analysis of expenditure and **productivity** within the EU's other business services sector shows very different situations between the investigation and security activities and industrial cleaning subsectors on one hand, and the miscellaneous business activities subsector on the other hand. Investment by the EU's miscellaneous business activities subsector was valued at EUR 9.1 billion in 2006, leading to an investment rate of 9.6%, far above the 3.5% rate for investigation and security activities and 3.7% rate for industrial cleaning.

An analysis of operating expenditure showed an equally remarkable difference, with **personnel costs** accounting for 67.0% of operating expenditure for the investigation and security activities subsector and the industrial cleaning subsector, while these costs represented less than half this share, just 29.7%, for the miscellaneous business activities subsector.

The EU's miscellaneous business activities subsector recorded the highest apparent **labour productivity** and average personnel costs of the three subsectors in 2006, as well as the highest wage adjusted labour productivity ratio (132.4%). The apparent labour productivity ratio and the average personnel costs for the industrial cleaning subsector were particularly low, respectively the second and fourth lowest levels of these two ratios among all NACE groups within the non-financial business economy in 2005 or 2006, reflecting the high incidence of part-time work in this subsector. The wage adjusted labour productivity ratio is less influenced by the incidence of part-time work, and this ratio was 112.4% for industrial cleaning and 113.0% for investigation and security activities, both among the five lowest ratios within the non-financial business economy NACE groups in 2005 or 2006.

Data sources and availability

The main part of the analysis in this article is derived from structural business statistics (SBS), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other possible data sources include **short-term statistics (STS)** and the **Labour force survey (LFS)**. In addition, use has also been made of specialist sources for particular areas, notably transport, energy, **research and development**, environment, tourism and **Information society statistics**.

Context

The freedom to provide services and the freedom of establishment are central principles to the [internal market](#) for services and are set out in the [EC Treaty](#) . They guarantee EU enterprises the freedom to establish themselves in other Member States, and the freedom to provide services on the territory of another EU Member State. The [Directive on services in the internal market](#) aims to achieve a genuine internal market in services, removing legal and administrative barriers to the development of services activities between Member States. The Directive was to be implemented by Member States by the end of 2009 at the latest. As well as covering most business services (with the notable exception of services of temporary work agencies), the Directive applies to a wide variety of services including industrial and construction activities, as well as [distributive trades](#) , [hotels](#) and restaurants, travel agents, real estate and renting services.

Services to buildings and landscape activities statistics - NACE Rev. 2

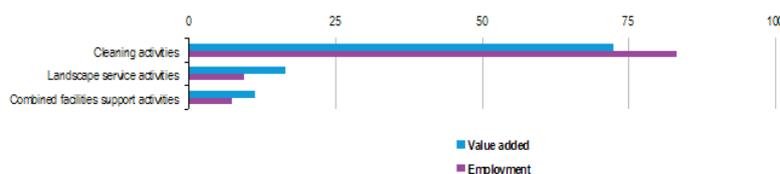

Data from April 2012. Most recent data: Further Eurostat information, Main tables and Database .

This article presents an overview of statistics for the services to buildings and landscape activities sector in the European Union (EU) , as covered by NACE Rev.2 Division81.

	Value
Main indicators	
Number of enterprises (1 000)	339
Number of persons employed (1 000)	4 065
Turnover (EUR million)	118 371
Purchases of goods and services (EUR million)	45 566
Personnel costs (EUR million)	57 534
Value added (EUR million)	73 002
Gross operating surplus (EUR million)	15 468
Share in non-financial business economy total (%)	
Number of enterprises	1.6
Number of persons employed (1)	3.0
Value added (1)	1.3
Derived indicators	
Apparent labour productivity (EUR 1 000 per head)	18.0
Average personnel costs (EUR 1 000 per head)	15.5
Wage adjusted labour productivity (%)	115.8
Gross operating rate (%)	13.1

Table 4b: Key indicators, services to buildings and landscape activities (NACE Division81), 2009 - Source: Eurostat (sbs_na_1a_se_r2)

Main statistical findings

Structural profile

Some 339 thousand enterprises operated within the services to buildings and landscape activities (Division81) sector in the EU-27 in 2009. Together they employed 4.06 million persons, equivalent to 3.0% of the total number of persons employed in the non-financial business economy (Sections B to J and L to N and Division95) or just over one third (33.7%) of the administrative and support services (Section N) workforce. These enterprises generated EUR73002 million of value added which was 1.3% of the non-financial business economy total and just over one fifth (20.9%) of the administrative and support services total.

The apparent labour productivity of the EU-27's services to buildings and landscape activities sector in 2009 was EUR18 thousand of value added per person employed, less than half the non-financial business economy average (EUR41.6 thousand) and some EUR11 thousand below the administrative and support services average. As such, the services to buildings and landscape activities sector recorded the third lowest level of apparent labour productivity among any of the NACE divisions (for which data are available) in the non-financial business economy.

This very low level of apparent labour productivity was mirrored in the average personnel costs for the EU-27's services to buildings and landscape activities sector, which stood at EUR15.5 thousand per employee in 2009, almost half the non-financial business economy average (EUR30.0 thousand per employee) and well below the administrative and support services average (EUR20.9 thousand).

The wage-adjusted labour productivity ratio combines the two previous indicators and shows the extent to which value added per person employed covers average personnel costs per employee. With very low productivity and average personnel costs, the EU-27's services to buildings and landscape activities sector had a low wage-adjusted labour productivity ratio – 115.8% in 2009 – which was below the non-financial business economy average (138.8%) and the administrative and support services average (139.1%).

The gross operating rate (which presents the relationship between the gross operating surplus and turnover) is one measure of operating profitability; it stood at 13.1% for the EU-27's services to buildings and landscape activities sector in 2009, which was about one third higher than the non-financial business economy average (9.7%), but below the administrative and support services average (15.2%).

Sectoral analysis

More than half (55.9%) of all the enterprises within the EU-27's services to buildings and landscape activities sector in 2009 were engaged in cleaning activities (Group81.2), while in excess of one third (36.2%) operated with landscape services (Group81.3) as their principal activity, leaving combined facilities support activities (Group81.1) as the activity of the remaining 8.0% of enterprises within this sector.

In output terms, the relative importance of cleaning activities in the EU-27's services to buildings and landscape activities sector rose to almost three quarters (72.4%) of sectoral value added in 2009, while the remaining added value was split between landscape service activities (16.4%) and combined facilities support activities (11.2%). There was an even greater shift towards cleaning activities when analysing the breakdown of employment within the EU-27's services to buildings and landscape activities sector in 2009. Some 83.2% of the workforce was employed within the cleaning activities subsector – emphasising the relative importance of labour input to this activity and also possibly reflecting high rates of part-time employment; there were 3.38 million persons employed within the EU-27's cleaning activities workforce in 2009. The relative share of the landscape service activities subsector was 9.4%, considerably lower than for its sectoral share of enterprises or value added, confirming the small average employment size of enterprises (an average of 3.1 persons employed per enterprise) in this subsector relative to the two other subsectors. The remaining 7.4% of the services to buildings and landscape activities sector's workforce were employed within combined facilities support activities.

All three of the subsectors within the EU-27's services to buildings and landscape activities sector recorded relatively low levels of apparent labour productivity in 2009, below the average for the non-financial business economy (EUR41.6 thousand per person employed) and – with the exception of landscape service activities (EUR31 thousand per person employed) – below the average for administrative and support service activities (EUR29 thousand per person employed). EU-27 apparent labour productivity for the cleaning activities subsector was particularly low (EUR16 thousand per person employed). Indeed, this was the joint third lowest level of apparent labour productivity – alongside the manufacture of wearing apparel, except fur apparel (Group14.1) – among all of the NACE groups that make-up the non-financial business economy, higher only than for beverage serving activities (Group56.3) and retail sales via stalls and markets (Group47.8).

Alongside relatively low levels of apparent labour productivity, the three services to buildings and landscape subsectors also had relatively low average personnel costs that were below the EU-27 non-financial business economy average. Average personnel costs per employee peaked at EUR24.2 thousand for the landscape service activities subsector in 2009, some EUR0.6 thousand per employee higher than for combined facilities support activities. The largest subsector – cleaning activities – recorded the lowest average personnel costs, at EUR14.0 thousand per employee; the fifth lowest value among any of the NACE groups within the non-financial business economy.

As EU-27 average personnel costs were proportionally not as low as apparent labour productivity in 2009, the resulting wage-adjusted labour productivity ratios for these three subsectors were all below the non-financial business economy average (138.8%). The highest wage-adjusted labour productivity ratio (128.4%) was recorded for landscape service activities, while the ratios for combined facilities support activities (115.6%) and cleaning activities (111.8%) were somewhat lower.

The pattern of relatively low productivity ratios was reversed when analysing gross operating profitability, as gross operating rates were higher than the non-financial business economy average (9.7%) for two of the three subsectors within the services to buildings and landscape activities sector. The EU-27 gross operating rate for cleaning activities was 11.7%, although operating profitability (using this measure) rose considerably higher for landscape service activities (20.1%). The only exception was combined facilities support activities, where the gross operating rate was slightly (0.4 percentage points) below the non-financial business economy average.

Country analysis

Germany had the highest share (22.2%) of EU-27 value added within the services to buildings and landscape activities sector in 2009, with added value of EUR16219 million. This was considerably higher than the shares recorded by the United Kingdom, France, Spain and Italy – although all four of these Member States also registered double-digit shares of EU-27 value added. Germany had the highest share of value added for both the cleaning activities subsector (20.1%) and the landscape service activities subsector (31.4%), although the

added value generated in the United Kingdom's combined facilities support activities subsector (39.0% of the EU-27 total) was higher than in Germany.

The German services to buildings and landscape activities workforce of just over a million persons was the largest in the EU-27, accounting for in excess of one quarter (25.2%) of the sectoral total in 2009. Around three quarters (75.1%) of the EU-27's services to buildings and landscape activities workforce worked in one of five Member States – Germany, the United Kingdom, Spain, Italy and France (note that the data for the latter are in terms of employees and not persons employed).

In value added terms, Finland and Spain were the most specialised Member States in the services to buildings and landscape activities sector in 2009, as this sector generated 2.0% and 1.9% respectively of non-financial business economy value added. Finland was particularly specialised in the combined facilities support activities subsector, while Spain was the most specialised Member State for cleaning activities, and Germany for landscape service activities.

All but one of the Member States reported relatively low wage-adjusted labour productivity ratios for services to buildings and landscape activities in 2009. Latvia (178.5%) was the only country where the wage-adjusted labour productivity ratio for this sector was above the national non-financial business economy average; it also recorded the highest ratio. At the other end of the range, Sweden was the only Member State to record a wage-adjusted labour productivity ratio for services to buildings and landscape activities that was below 100%.

There were relatively high levels of operating profitability for services to buildings and landscape activities, as demonstrated by the fact that only three Member States – Ireland, Portugal and Spain – reported that their gross operating rates in this sector were below national averages for the whole of the non-financial business economy. In contrast, the gross operating rate (26.9%) for Latvian services to buildings and landscape activities was the highest among the Member States and was some 2.8 times as high as the national non-financial business economy average (the biggest relative difference among the Member States).

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the services to buildings and landscape activities sector in the EU, as covered by NACE Rev.2 Division81.

This division includes the provision of a combination of support services within a client's facilities, a variety of cleaning activities as well as landscape activities. Combined facilities support activities involve the provision of a combination of support services within a client's facilities. These include general interior cleaning, maintenance, rubbish disposal, guard and security, mail routing, reception, laundry and related services to support operations within facilities. These support activities are performed by operating staff, which is not involved with or responsible for the core business or activities of the client.

Cleaning activities include the cleaning of all types of buildings, exterior cleaning of buildings, specialised cleaning activities for buildings or other specialised cleaning activities, cleaning of industrial machinery, cleaning of the inside of road and sea tankers, disinfecting and extermination activities for buildings and industrial machinery, bottle cleaning, street sweeping, snow and ice removal.

Landscape service activities include planting, care and maintenance of parks and gardens for private and public housing, industrial and commercial buildings, schools, hospitals, administrative buildings, church buildings and so on, as well as municipal grounds such as cemeteries. Also included is greenery for transport infrastructure, sports and playgrounds, around ponds, swimming pools and watercourses, and protective plants – for example against noise, wind or erosion.

This NACE division is composed of three groups:

- combined facilities support activities (Group81.1);
- cleaning activities (Group81.2);
- landscape service activities (Group81.3).

Excluded from combined facilities support activities is the provision of a single (only one) support service, as well as the provision of management and operating staff for the complete operation of a client's establishment (such as a hotel or restaurant). Excluded from cleaning activities are steam cleaning and blasting and similar activities for building exteriors (which are part of [specialised construction activities](#) , Division43) and automobile cleaning and car wash (part of [motor trades](#) , Division45). Excluded from landscape service activities are [construction activities](#) for landscaping purposes which are included within SectionF and landscape design and architecture activities (part of [architectural and engineering activities, technical testing and analysis](#) , Division71).

Sewerage statistics - NACE Rev. 2

Data from April 2012. Most recent data: Further Eurostat information, Main tables and Database .

This article presents an overview of statistics for the sewerage sector in the [European Union \(EU\)](#) , as covered by [NACE Rev.2 Division 37](#). Sewerage and [water supply](#) are strongly related, with many enterprises offering both water supply and wastewater services, where sometimes the fees paid by users for water supply include the service of treating the resulting wastewater.

Table 2b: Key indicators, sewerage (NACE Division 37), 2009 - Source: Eurostat (sbs_na_ind_r2)

Main statistical findings

Structural profile

There were 9670 enterprises operating with sewerage (Division37) as their main activity in the EU-27 in 2009. Together they employed 139.6 thousand persons and generated EUR12646 million of value added. This relatively small sector employed 0.1% of the total number of persons employed in the non-financial business economy (Sections B to J and L to N and Division 95) and contributed 0.2% of its total value added. Its share within water supply, sewerage, waste management and remediation activities (Section E) was 11.0% in employment terms and 16.1% in value added terms.

The apparent labour productivity of the EU-27's sewerage sector in 2009 was EUR91 thousand per person employed, more than double the non-financial business economy average of EUR41.6 thousand per person employed and also well above the water supply, sewerage, waste management and remediation activities average (EUR62 thousand per person employed). Despite this high apparent labour productivity, average personnel costs within the EU-27's sewerage sector were only slightly elevated, at EUR33.7 thousand per employee compared with a EUR30.0 thousand per employee average for the non-financial business economy and a EUR31.5 thousand per employee average for water supply, sewerage, waste management and remediation activities. As a result, the sewerage sector posted a wage-adjusted labour productivity ratio of 269.0%, which was the sixth highest for any NACE division within the EU-27's non-financial business economy in 2009, and far above the non-financial business economy average (138.8%) and the water supply, sewerage, waste management and remediation activities average (196.8%).

The gross operating rate (the relation between the gross operating surplus and turnover) stood at 38.1% for the EU-27's sewerage sector in 2009, nearly four times as high as the average for the non-financial business economy (9.7%) and close to double the water supply, sewerage, waste management and remediation activities average (20.9%). This was the second highest level of profitability (according to this measure) among the NACE divisions within the non-financial business economy, lower only than that recorded for real estate activities (Division 68). It should be noted that this measure does not take account of depreciation or financial expenditure, which are typically higher in capital-intensive activities such as sewerage.

Country analysis

In employment terms, Germany recorded the highest share (27.7%) of the EU-27 workforce within the sewerage sector in 2009, slightly ahead of Poland (23.7%). The relative importance of the sewerage sector was highest in Poland, as it employed 0.4% of the Polish non-financial business economy workforce in 2009, around four

times the average for the EU-27. The next most specialised Member States (in employment terms) were Latvia (0.3% of non-financial business economy employment), Germany and Cyprus (both 0.2%). Generally the same Member States were also the most specialised in value added terms, although data is not available for Germany.

The high wage-adjusted labour productivity ratio recorded for the EU-27 in the sewerage sector in 2009 was pulled up by a very high ratio (484.1%) for the United Kingdom and also by Austria, Cyprus and Denmark, where the wage-adjusted labour productivity ratios for the sewerage sector were more than 100 percentage points higher than national averages for the whole of the non-financial business economy.

A similar situation was observed for the gross operating rate, as the United Kingdom recorded a rate of 61.2% which was the highest gross operating rate recorded in the United Kingdom in 2009 among all of the non-financial business economy NACE divisions; Latvia's gross operating rate of 45.3% was also the highest among all non-financial business economy NACE divisions in Latvia. Most Member States recorded gross operating rates for the sewerage sector that were above their non-financial business economy averages, the exceptions (among Member States with data available) were Ireland, the Netherlands and most notably Bulgaria where a negative rate was observed.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the sewerage sector in the EU, as covered by NACE Rev.2 Division37. This division includes the operation of sewer systems or sewage treatment facilities, the collecting and transporting of human or industrial wastewater from one or several users (as well as the collection of rain water) by means of sewerage networks, collectors, tanks and other means of transport (sewage vehicles and so on). Also included are the emptying and cleaning of cesspools and septic tanks, sinks and pits from sewage; the servicing of chemical toilets, treatment of wastewater by means of physical, chemical and biological processes like dilution, screening, filtering, sedimentation and so on, maintenance and the cleaning of sewers and drains.

This division contains one group and one class only and so there is no analysis of subsectors in this article.

The decontamination of surface water and groundwater at the place of pollution (part of [remediation and other waste management services](#) , Division39) is excluded.

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers shipbuilding, corresponding to NACE Group 35.1, which is part of the [transport equipment](#) sector. The activities covered in this article are the building and repairing of ships and boats.

Note that, unlike for motor vehicles, this activity does not include the manufacture of parts or (marine) engines.

	Highest value added (1)		Largest number of persons employed (1)		Most specialised: share in non-financial business economy (%) (2)			
	Country	(EUR million)	(% of EU-27)	Country	(thou-sand)	(% of EU-27)	Country	Value added
1	Italy	2 036	18.1	Italy	43.0	14.3	Romania	0.7

Table 1: Building and repairing of ships and boats (NACE Group 35.1). Structural profile: ranking of top five Member States in terms of value added and persons employed, 2006

Main statistical findings

Structural profile

	Prodcom code	Production value (EUR million)	Rounding base (EUR million)	Volume of sold production (thousand)	Unit of volume	Rounding base (million)
Bulk carriers, general cargo ships, container ships, ro-ro vessels, car carriers, gas carriers, etc., and other vessels for the transport of both persons and goods, sea-going	35.11.24.70	4 570	-	3 497	GT	-
Cruise ships, excursion boats for people, ferry boats, sea-going	35.11.21.30	4 225	-	841	GT	-
Sea-going motorboats for pleasure or sports (excluding outboard motorboats)	35.12.13.30	3 300	100	28	units	7
Sea-going sailboats for pleasure or sports	35.12.11.30	1 980	-	13	units	-
Rigid boats > 100 kg in weight and 7.5 m in length (including outboard motorboats, rowing boats and canoes)	35.12.13.97	1 408	-	9	units	-

(1) Excluding products of a generic nature (other), sales of services such as repair, maintenance and installation; estimates; threshold of production value set at EUR 1 billion; the rounding base indicates the magnitude of the rounding employed to protect confidential cells (in the case of PRODCOM code 35.12.13.30, the value lies within the range +/- EUR 100 million of the reported value).
Source: Eurostat (PRODCOM)

Table 2: Ships and boats (CPA Group 35.1). Production of selected products, EU-27, 2007 (1)

In 2006, there were 20.8 thousand [enterprises](#) in the [Transport and storage statistics](#)'s sector for the building and repairing of ships and boats (NACE Group 35.1). These enterprises generated EUR 11.2 billion of [value added](#) and employed an estimated 300.0 thousand persons. This sector contributed 5.8% of transport equipment (NACE Subsection DM) value added, and 9.5% of the transport equipment workforce. The building and repairing of ships (NACE Class 35.11) was the largest subsector, with EUR 8.0 billion of value added and a workforce of an estimated 230.0 thousand persons, with the building and repairing of pleasure and sporting boats (NACE Class 35.12) making up the rest of the sector.

Italy and France were the largest producers (in value added terms) in this sector within the Transport and storage statistics. In terms of [employment](#) the importance of this sector in Romania and Poland can be observed, as over 30.0 thousand persons worked in this sector in each of these countries, more than one tenth of the Transport and storage statistics total. Those Member States with a coastline tended to report relatively high value added specialisation in this sector, notably in the [Baltic Member States](#), Romania, Bulgaria, Finland and Greece. In fact, in Bulgaria, Lithuania and Finland more than half of transport equipment value added

was generated in this sector.

Output from the building and repairing of ships and boats declined in the Transport and storage statistics most years between 1997 and 2004, with an average contraction of 2.3% per year. During this period annual growth was only recorded in 2001. From 2004 onwards output expanded, only slightly in 2005, but more strongly in 2006 and 2007.

Expenditure and productivity

Gross **tangible investment** in the transport and storage statistics's sector for the building and repairing of ships and boats was EUR 1.1 billion in 2005, resulting in an **investment rate** of 11.0%. Personnel costs accounted for 21.9% of **operating expenditure** in this sector in 2006, above the transport equipment manufacturing average (15.9%). Among the transport equipment manufacturing subsectors the [[Transport and storage statistics's building and repairing of ships and boats sector recorded the lowest average **personnel costs** (EUR 30.2 thousand per employee), apparent **labour productivity** (EUR 37.4 thousand per person employed) and **wage-adjusted labour productivity ratio** (124.1%). Romania (95.6%) and Denmark (57.8%) both recorded wage-adjusted labour productivity ratios below parity in this sector, indicating that value added per person employed was lower than average personnel costs, while Ireland recorded a very large, negative ratio as Irish value added in this sector was negative.

Data sources and availability

The main part of the analysis in this article is derived from **structural business statistics (SBS)** , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include the **PRODCOM** statistics on the production of manufactured goods.

Context

The transport equipment manufacturing sector is central to economic development, as it provides the means for transporting both individuals and goods. Demand for transport equipment has risen as the volume of goods transported and the distance travelled by passengers have expanded greatly – see the article on **transport and storage statistics** for information on transport flows.

The issue of sustainable development is likely to play an important role in future product developments, as transport equipment manufacturers try to meet demands for more environmentally friendly transport solutions, for example, engines with lower fuel consumption or emissions.

Most transport equipment manufacturing activities are structured on the basis of complex pyramidal relationships between major manufacturers and several tiers of component suppliers, ranging from systems suppliers down to very small, specialised manufacturers that may provide a single component for a vehicle. It is common to find clusters of enterprises concentrated in regions around the leading producers.

Table 4b: Key indicators, specialised construction activities (NACE Division 43), 2009 - Source: Eurostat (sbs_na_con_r2)

Main statistical findings

Structural profile

In terms of a simple count of the number of enterprises, the specialised construction activities sector (Division 43) was by far the largest of the three NACE divisions within **construction** (Section F) in the EU-27 in 2009. In total there were 2.2 million enterprises active in this sector, equivalent to 69.3% of all construction enterprises and more than one in ten (10.6%) enterprises in the whole of the **non-financial business economy** (Sections B to J and L to N and Division 95). These enterprises employed 8.7 million persons, equivalent to 6.5% of the non-financial business economy workforce and 59.2% of the construction workforce. They generated EUR 268 404 million of value added which was approximately 4.8% of the non-financial business economy total and 52.4% of the construction total. These figures suggest that the specialised construction activities sector is composed of a very large number of relatively small enterprises.

The **apparent labour productivity** of the EU-27's specialised construction activities sector in 2009 was EUR 31 thousand per person employed. This was the lowest apparent labour productivity among the three construction NACE divisions and was around 25% lower than the non-financial business economy average (EUR 41.6 thousand per person employed). Despite this low level of apparent labour productivity, **average personnel costs** within the EU-27's specialised construction activities sector were, at EUR 31.3 thousand per employee, above the non-financial business economy average (EUR 30.0 thousand per employee) and the construction average (EUR 30.6 thousand per employee). Low apparent labour productivity and high average personnel costs resulted in a low **wage-adjusted labour productivity ratio** – an indicator that is derived by combining the two previous measures. The wage-adjusted labour productivity ratio for the EU-27's specialised construction activities sector in 2009 was just 98.5%, indicating that average personnel costs were higher than apparent labour productivity, a situation repeated in only three other NACE divisions within the non-financial business economy in 2009.

Often a low wage-adjusted labour productivity ratio is accompanied by a low **gross operating rate** (the relation between the **gross operating surplus** and **turnover**), but this was not the case for the EU-27's specialised construction activities sector where the gross operating rate was 11.4%, which was above the non-financial business economy average (9.7%) and the construction average (10.6%). This combination of a wage-adjusted labour productivity ratio below 100% and a high gross operating rate is unusual – it also occurs for the **computer and personal and household goods repair activity** (Division 95). The relatively high gross operating surplus for the specialised construction activities sector occurs because of a combination of elements: there are many working proprietors and/or unpaid family workers in this sector, and so the share of paid employees in the total number of persons employed is low (69.7% compared with a construction average of 75.9%); this leads to a relatively low level of total (rather than average) personnel costs, which in turn results in a relatively high gross operating

surplus. Nevertheless, it should be borne in mind that the large number of working proprietors and unpaid family workers need to be recompensed from the gross operating surplus, which should also cover depreciation and financial expenditure.

Sectoral analysis

Within the EU-27 the two largest specialised construction subsectors were electrical, plumbing and other construction installation activities (Group43.2, hereafter referred to as the construction installation subsector) and building completion and finishing (Group43.3). Together they contributed around three quarters of sectoral value added and employment in the EU-27 in 2009 – see Figure 1. The third largest subsector was other specialised construction activities (Group43.9) which contributed around one fifth of sectoral employment and value added, between three and four times the size of the smallest subsector, namely the demolition and site preparation subsector (Group43.1).

The productivity of the four subsectors varied from EUR24 thousand of value added per person employed for the EU-27's building completion and finishing subsector to EUR40 thousand per person employed for demolition and site preparation. The range in average personnel costs was much narrower, although the highest and lowest values were recorded in the same subsectors: from a low of EUR30.2 thousand per employee for building completion and finishing rising to EUR33.0 thousand per employee for demolition and site preparation.

The low wage-adjusted labour productivity ratio for the EU-27's specialised construction activities sector as a whole was pulled downwards by the building completion and finishing subsector, as the ratio for this activity was just 79.4%; this was not only the lowest wage-adjusted labour productivity ratio among the EU-27's construction NACE groups in 2009, but also the lowest among all NACE groups within the non-financial business economy. The wage-adjusted labour productivity ratio was also below the construction average of 113.9% for the other specialised construction activities subsector and for the construction installation subsector, while it peaked at 122.5% for demolition and site preparation, which was nevertheless below the non-financial business economy average.

In contrast to the wage-adjusted labour productivity ratio, the gross operating rate for these four subsectors within the EU-27 was within a narrow range: for the other specialised construction activities and construction installation subsectors the gross operating rate was close to the construction average (10.6%); for the two remaining subsectors it reached close to 13%.

Country analysis

In value added terms, France had the largest specialised construction activities sector among the Member States in 2009 and recorded the highest level of value added among the Member States across each of the four subsectors. France's share of EU-27 value added averaged 23.5% for the whole of the specialised construction activities sector, and rose as high as 32.7% for the other specialised construction activities subsector.

The relative importance of specialised construction activities was also highest in France, as this sector contributed 7.7% to non-financial business economy value added in 2009, ahead of Luxembourg (7.0%) and Denmark (6.5%). The Member States that were least specialised in the specialised construction activities sector in 2009 were Romania, Latvia, Lithuania, Hungary and Slovakia, where this sector contributed less than 3.0% of non-financial business economy value added.

The very low wage-adjusted labour productivity ratio recorded for the EU-27's specialised construction activities sector in 2009 was a reflection of particularly low ratios in several Member States: two of the largest Member States, Italy and Spain, recorded wage-adjusted labour productivity ratios below 100%, as did Greece and Ireland. Only one Member State (among those with data available) recorded a wage-adjusted labour productivity ratio for the specialised construction activities sector that was around the same level as its national average for the whole of the non-financial business economy, namely Bulgaria.

Despite recording the second lowest wage-adjusted labour productivity ratio among the Member States, Greece registered a gross operating rate of 23.2% for specialised construction activities in 2009; this was more than double the EU-27 average and the highest ratio among the Member States. In contrast, Ireland recorded the

third lowest wage-adjusted labour productivity ratio (below 100%), but its gross operating rate was just 0.9%, the lowest among the Member States.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the specialised construction activities sector in the EU, as covered by NACE Rev.2 Division43. This division includes specialised construction activities, also referred to as special trades, in other words, the construction of parts of buildings and civil engineering works or preparation therefore. These activities are usually specialised in one aspect common to different structures, requiring specialised skills. Specialised construction activities are mostly carried out under subcontract, but especially in repair construction it is done directly for the owner of the property. Building finishing and building completion activities are usually performed at the site of the construction, although parts of the job may be carried out in a special (work)shop.

Demolition and site preparation includes activities of preparing a site for subsequent construction activities, including the demolition/wrecking and removal of previously existing structures, earth moving, excavation, landfill, levelling and grading of construction sites, trench digging, rock removal, blasting, and so on. Also included is building site drainage, drainage of agricultural or forestry land, site preparation for mining and test drilling and boring.

Construction installation activities include electrical, plumbing, heating and air-conditioning installation, as well as the installation of elevators, escalators, automated and revolving doors, lightning conductors, vacuum cleaning systems as well as thermal, sound or vibration insulation.

Building completion and finishing includes: plastering; joinery installation such as doors, windows, frames, staircases, fitted kitchens, built-in cupboards, shop fittings, ceilings and movable partitions; fitting or laying of floor and wall coverings of wood, carpet, linoleum, stone, tiles or wallpaper; interior and exterior painting and glazing; cleaning of new buildings after construction and other building completion and finishing work.

Other specialised construction activities include roofing activities such as the erection of roofs and roof covering as well as specialisation in one aspect common to different kinds of structures, requiring specialised skill or equipment: the construction of foundations; damp proofing and water proofing works; de-humidification of buildings; shaft sinking; the erection of non-self-manufactured steel elements; bricklaying and stone setting; scaffolding; the erection of chimneys and industrial ovens; the construction of outdoor swimming pools; renting (with operator) of cranes and other building equipment which cannot be allocated to a specific construction type, with operator.

This NACE division is composed of four groups:

- demolition and site preparation (Group43.1);
- electrical, plumbing and other construction installation activities (Group43.2);
- building completion and finishing (Group43.3);
- other specialised construction activities (Group43.9).

The information presented in this article does not cover the decontamination of soil (which forms part of [remediation activities and other waste management services](#) , Division39), the drilling of production oil or gas wells (included within the [extraction of crude petroleum and natural gas](#) , Division06), or oil and gas field exploration, geophysical, geological and seismic surveying (included in [architectural and engineering activities](#);

[technical testing and analysis](#) , Division71). Furthermore, the renting of construction machinery and equipment without operator (classified within [rental and leasing activities](#) , Division77) is also excluded.

Specialised in-store food retail trade statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers specialised in-store food retail trade, corresponding to NACE Group 52.2, which is part of the [retail trade and repair](#) sector. The activities covered in this article are the retail sale in specialised stores of:

- food;
- beverages;
- tobacco.

	Enterprises (thousand)	Turnover (EUR million)	Value added (EUR million)	Persons employed (thousand)	Share in total (%)	
					Value added	Persons employed

Table 3: Specialised in-store food retailing (NACE Group 52.2). Expenditure, productivity and profitability, EU-27, 2006

The EU-27's specialised food retailing sector (NACE Group 52.2) consisted of 0.5 million enterprises in 2006 which generated EUR 130 billion of turnover and EUR 26 billion of value added. Therefore, specialised food retailing contributed 6.2% of retail trade and repair (NACE Division 52) value added, while its contribution to retail trade and repair turnover was 5.7%: both of these shares were well below the sector's 13.2% share of the total number of enterprises in retail trade and repair, indicating a large number of relatively small (on average) enterprises in the specialised food retailing sector.

The specialised food retailing sector employed 1.45 million people in the EU-27, equivalent to 8.3% of the retail trade and repair workforce. The share of employees in persons employed was 64.1%, substantially below the retail trade and repair average (79.7%), and in fact, the fifth lowest rate of all NACE groups within the non-financial business economy.

The largest subsector in the EU-27's specialised food retailing sector was the retail sale of meat and meat products (NACE Class 52.22), which alone provided around one quarter of the total turnover, value added and employment.

Overall, specialised food retailing was particularly important in Spain and Italy, which had higher turnover, value added and employment than any other Member State. Unsurprisingly they were both among the most specialised of the Member States¹³¹ in this sector, only behind Greece, where specialised food retailing contributed 1.3% to the non-financial business economy in terms of value added.

¹³¹Bulgaria, Cyprus, Luxembourg, Poland and Romania, 2005; Malta and the Netherlands, not available.

Among the Member States¹³² some individual subsections have a particular significance. The specialised retailing of beverages was important in Estonia, where it contributed more than three quarters of specialised food retailing turnover, slightly less than five times the EU-27 average. Specialised retailing of fruit and vegetables contributed nearly two fifths of Cypriot turnover in this sector, close to four times the EU-27 average, while in Austria specialised retailing of tobacco generated 63.7% of the sector's turnover, 3.7 times as much as the EU-27 average.

Annualised short-term statistics show generally weak growth in turnover for the EU-27's specialised food retailing sector over the period 1998 to 2007. Indeed, the index registered a negative rate of change in 2004 (-0.4%) and only once, in 2001, did growth exceed 3%. Over the whole period, the index averaged growth of 1.4% per year, just over one third of the average rate (3.6%) for retail trade and repair during the same period.

Expenditure and productivity

In 2006 specialised food retailing had a slightly lower than average (for retail trade and repair) [investment rate](#) in the EU-27, 12.6%, resulting from investments valued at EUR 3.3 billion.

[Personnel costs](#) represented 11.4% of the [operating expenditure](#) of specialised food retailers. The subsector of the retail sale of bread, cakes, flour confectionery and sugar confectionery (NACE Class 52.24) recorded a much higher share of personnel costs, 23.7%, twice the sectoral average. On the other hand, a particularly low share of personnel costs (in operating expenditure) was recorded for the retail sale of tobacco products and of beverages (NACE Classes 52.25 and 52.26), both sectors where the share of the purchases of goods and services may be inflated by consumption taxes.

EU-27 apparent [labour productivity](#) for the specialised food retailing sector was EUR 17.9 thousand per person employed in 2006, while average personnel costs were EUR 14.3 thousand per employee. Both values were particularly low: the productivity indicator was the seventh lowest of all non-financial business economy NACE groups, while average personnel costs were sixth lowest. Nevertheless the resulting [wage-adjusted labour productivity ratio](#) for this sector was 125.4% in 2006, only slightly below the retail trade and repair average (128.1%). Among the NACE classes that compose the sector, particularly high apparent labour productivity was recorded for the retail sale of tobacco products (NACE Class 52.26), and despite higher than average personnel costs this subsector recorded the highest wage-adjusted labour productivity ratio, 171.4%.

Among the Member States¹³³, wage adjusted labour productivity ratios for specialised food retailing were below national non-financial business economy averages in all of the Member States in 2006, while in Greece and Hungary this ratio was below 100%, indicating that apparent labour productivity was lower than average personnel costs.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include [short-term statistics \(STS\)](#).

Context

Retailing is typically the final stage of distribution between producers and consumers. Since the development of the Internet, there has been an increasing use of commerce via the web. As such, there has been a gradual shift from traditional methods of purchasing from stores or markets to purchasing remotely. According

¹³²Bulgaria, Estonia, Lithuania, Luxembourg and Poland, 2005; Ireland, Slovakia, Finland and Sweden, incomplete; Malta, not available.

¹³³Bulgaria, Cyprus, Luxembourg, Poland and Romania, 2005; Malta and the Netherlands, not available.

to Eurostat's information society statistics, some 12% of the turnover of distributive trades (including motor trades (NACE Division 50) and wholesale trades (NACE Division 51), as well as retail trade and repair) enterprises with ten or more persons employed was derived from [e-commerce](#) in 2008. According to the same source, one quarter of the EU-27's population ordered or bought goods or services for private use through the Internet in 2008 (during the three months preceding the survey). Note that these figures refer to goods and services supplied to individuals by all sectors of the economy, not just enterprises that are specialised in retail sales.

In October 2008, the [European Commission](#) put forward a [proposal COM\(2008\) 614](#) for a Directive on consumer rights, to try to make purchases easier and safer, whether in-store or not. The proposal covers the provision of price information, protection against late delivery and non delivery, as well as setting out rights on issues such as cooling-off periods, returns, refunds, repairs and guarantees and unfair contract term.

Food retailing specialists are generally small retail outlets that do not belong to national or international chains, for example, fruit and vegetable shops, bakers, butchers and fishmongers. Contrary to many non-food items, food is a typically inelastic good, which means that when prices rise, consumers generally do not cut back as much on the total quantity purchased, although price changes may influence the choice of brand or retailer chosen by individual customers.

Specialised in-store non-food retail trade statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers specialised in-store non-food retail trade, corresponding to NACE Groups 52.3 and 52.4, which are part of the [retail trade and repair](#) sector. The activities covered in this article are:

- dispensing chemists, retailers of medical, orthopaedic, cosmetic and toilet articles (NACE Group 52.3);
- other specialised in-store retailing of new goods (NACE Group 52.4), such as shops selling clothes, shoes, furniture, books or electrical items.

This sub-sector does not include the retailing of second-hand goods in stores, which is covered in [the article on second-hand goods in-store retail trade](#).

	Enterprises (thousand)	Turnover (EUR million)	Value added (EUR million)	Persons employed (thousand)	Share in total (%)

Table 2: Specialised in-store new goods retailing other than food (NACE Groups 52.3 and 52.4). Structural profile: ranking of top five Member States in terms of value added and persons employed, 2006

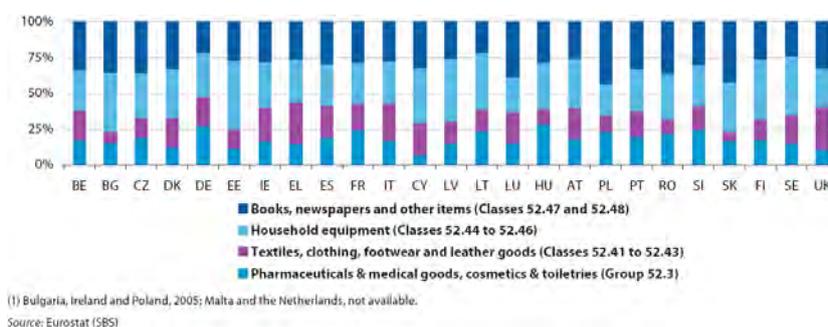

Figure 1: Specialised in-store new goods retailing other than food (NACE Groups 52.3 and 52.4). Breakdown of turnover, 2006 (%) (1)

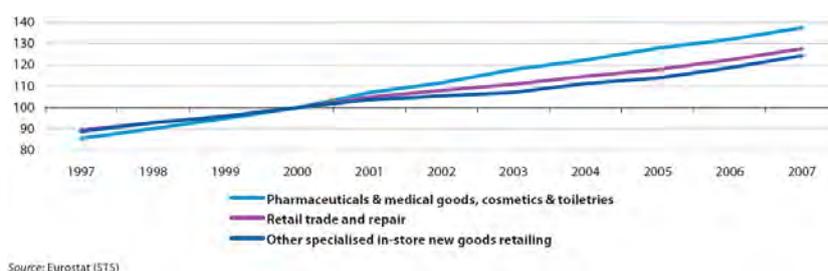

Figure 2: Specialised in-store new goods retailing other than food (NACE Groups 52.3 and 52.4). Index of turnover, EU-27 (2000=100)

In 2006, the EU-27's sector of specialised retailing other than food (NACE Groups 52.3 and 52.4) consisted of 2.0 million enterprises which generated in excess of EUR 1000 billion of turnover and EUR 210.9 billion of value added (2005). As such, this sector contributed more than half (53.8%) of the total value added generated in the EU-27's retail trade and repair sector (NACE Division 52).

The sector of specialised retailing other than food employed 8.6 million persons in 2006, equivalent to 49.0% of the EU-27's retail trade and repair total. Paid employees accounted for 78.6% of all persons employed in 2006, close to the retail trade and repair average. The paid employment rate was highest (87.5%) in the activity of dispensing chemists (NACE Class 52.31), and lowest (52.4%) for the retail sale of textiles (NACE Class 52.41).

Among the two NACE groups that make up specialised retailing other than food, the subsector concerning other specialised retailing of new goods (NACE Group 52.4) was by far the largest in terms of value added and employment, contributing at least four fifths of the sectoral total for both of these indicators.

Turning to the Member States, specialised retailing other than food was largest in Germany in terms of value added and employment, followed by the United Kingdom. The contribution of both of these Member States was a little under one fifth of the EU-27 value added total, while they contributed less in employment terms. In terms of this sector's contribution to non-financial business economy value added, Greece and Cyprus were the most specialised Member States¹³⁴, as this sector accounted for around 6.5% of their non-financial business economy value added. When looking at a breakdown of retailing turnover among four main groupings of non-food activities¹³⁵, the specialised retailing of household equipment (NACE Classes 52.44 to 52.46) was the largest in 14 of the Member States, reaching a 48.0% share in Estonia. The specialised retailing of books, newspapers and other items (NACE Classes 52.47 and 52.48) was the largest in the remaining 11 Member States, with Poland recording a 43.5% share of specialised retailing other than food in these activities. Turning to the smaller groupings, specialised retailing of textiles, clothing, footwear and leather goods (NACE Classes 52.41 to 52.43) generated close to 30% of turnover in the United Kingdom and Greece, while dispensing chemists, retailers of medical, orthopaedic, cosmetic and toilet articles (NACE Group 52.3) contributed more than one quarter of the sector's value added in Hungary and Germany.

Annualised short-term statistics show the turnover index in the two NACE groups covered by the EU-27's

¹³⁴Bulgaria, Cyprus, Poland and Romania, 2005; Malta and the Netherlands, not available.

¹³⁵Bulgaria, Ireland and Poland, 2005; Malta and the Netherlands, not available.

sector of specialised retailing other than food. In both activities there was uninterrupted growth over the period 1997 to 2007. Dispensing chemists, retailers of medical, orthopaedic, cosmetic and toilet articles recorded average turnover growth of 4.9% per year over the period observed. In contrast, sales grew at a somewhat slower pace for other specialised retailing of new goods, with average growth of 3.4% per year (below the 3.6% average for the whole of retail trade and repair).

Expenditure and productivity

Specialised retailing other than food had the second highest level of **tangible investment** in the EU-27's retail trade and repair sector in 2006, valued at EUR 27.0 billion, 44.0% of the retail trade and repair total. The **investment rate** was 11.7% in 2005, 3.0 percentage points below the retail trade and repair average. Dispensing chemists, retailers of medical, orthopaedic, cosmetic and toilet articles recorded an investment rate of just 6.6% in 2006, in contrast to the rate of 13.0% (in 2005) recorded for other specialised retailing of new goods.

An analysis of **operating expenditure** shows that in the EU-27's sector of specialised retailing other than food some 14.0% of the total was dedicated to **personnel costs** in 2005, a share rising to 14.3% for other specialised retailing of new goods, and dropping to 13.4% in 2006 for dispensing chemists, retailers of medical, orthopaedic, cosmetic and toilet articles.

With apparent **labour productivity** of EUR 25.4 thousand per person employed in 2005 and personnel costs of EUR 18.9 thousand per employee, the **wage-adjusted labour productivity ratio** in the EU-27's sector of specialised retailing other than food averaged 134.9%: all three of these indicators were above the retail trade and repair average in the same year. The subsector concerning dispensing chemists, retailers of medical, orthopaedic, cosmetic and toilet articles recorded higher apparent labour productivity and average personnel costs in 2006, and the wage-adjusted labour productivity ratio in this subsector reached 152.7%.

Across all the Member States for which data are available¹³⁶, the lowest wage adjusted labour productivity ratio for specialised retailing other than food was 101.5%, recorded in Italy. None of the Member States recorded a wage adjusted labour productivity in specialised retailing other than food that was higher than the average for the non-financial business economy, the closest being in Slovakia and France.

Data sources and availability

The main part of the analysis in this article is derived from **structural business statistics (SBS)**, including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include **short-term statistics (STS)**.

Context

Retailing is typically the final stage of distribution between producers and consumers. Since the development of the Internet, there has been an increasing use of commerce via the web. As such, there has been a gradual shift from traditional methods of purchasing from stores or markets to purchasing remotely. According to Eurostat's information society statistics, some 12% of the turnover of distributive trades (including motor trades (NACE Division 50) and wholesale trades (NACE Division 51), as well as retail trade and repair) enterprises with ten or more persons employed was derived from **e-commerce** in 2008. According to the same source, one quarter of the EU-27's population ordered or bought goods or services for private use through the Internet in 2008 (during the three months preceding the survey). Note that these figures refer to goods and services supplied to individuals by all sectors of the economy, not just enterprises that are specialised in retail sales.

In October 2008, the **European Commission** put forward a **proposal COM(2008) 614** for a Directive on consumer rights, to try to make purchases easier and safer, whether in-store or not. The proposal covers the provision of price information, protection against late delivery and non-delivery, as well as setting out rights on issues such

¹³⁶Bulgaria and Poland, 2005; Malta and the Netherlands, not available.

as cooling-off periods, returns, refunds, repairs and guarantees and unfair contract term.

This article deals with the retailing of consumer non-durable, semi-durable and durable goods. Among the retailing of non-durable goods are pharmaceuticals, cosmetics and toilet articles, while semi-durable goods include items such as clothing and footwear. Electrical household appliances and radio and television equipment are examples of durable goods. Compared with food retailing, non-food retailing is more strongly influenced by the general [economic cycle](#) . Most non-food items are bought less frequently or at a certain period of the year, although there are examples (such as newspapers) of non-durable, non-food products that are purchased on a frequent basis.

Stone, abrasive and insulating materials production statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). The present article covers the production of stone, abrasive and insulating materials, which is part of the [other non-metallic minerals](#) sector. The activities covered in this article correspond to two different [NACE Rev 1.1](#) groups, which are:

- the working of stone (NACE Group 26.7), which includes the activities of cutting, shaping and finishing stone;
- the manufacture of miscellaneous non-metallic mineral products (NACE Group 26.8), which includes the production of abrasive products, non-metallic mineral yarns, and mineral insulating materials (for both heat or sound insulation).

	Enterprises (thousand)	Turnover (EUR million)	Value added (EUR million)	Persons employed (thousand)	Share in total (%)	
					Value added	Persons employed
Stone and miscellaneous non-metallic mineral products (2)	406	38 627	11 102	301.3	100.0	100.0
Cutting, shaping and finishing of ornamental and building stone	37.0	17 000	6 400	203.4	54.0	67.5
Other non-metallic mineral products (2)	3.7	21 627	5 102	97.9	46.0	32.5

Source: Eurostat (PRODCOM)

Table 2: Stone and miscellaneous non-metallic mineral products (CPA Groups 26.7 and 26.8). Production of selected products, EU-27, 2007 (1)

Working of stone

There were 37.0 thousand enterprises in the Member States for whom the working of stone (NACE Group 26.7) was their main activity in 2006. These enterprises employed 203.4 thousand persons, about one in every eight people (12.8%) within the total EU-27 workforce of other non-metallic mineral products manufacturing (NACE Division 26). From a turnover of EUR 17.0 billion, the EU-27's working of stone subsector created EUR 6.4 billion of added value, which represented 8.0% of the value added generated by the other non-metallic mineral products manufacturing sector as a whole.

Just over one half (51.2%) of the value added generated by the EU-27's working of stone subsector in 2006 was generated in Italy and Spain, two countries that were also amongst the most specialised in this activity. Among the Member States for which information is available¹³⁷, Portugal was the most specialised in this activity, the relative contribution of the working of stone subsector to non-financial business economy (NACE Sections C to I and K) value added being almost three times the EU-27 average in 2006.

The cumulative fall in the EU-27's production index for the working of stone in the period between 2001 and 2004 took output back close to its level recorded for 1997. In the three years through to 2007, however, the production index for the working of stone rose at a similar rate to the index for other non-metallic mineral products, resulting in an average rate of growth in output over the ten year period of 0.9% per year.

Tangible investment of EUR 0.9 billion in the EU-27's working of stone subsector in 2006 corresponded to 5.9% of investment across the other non-metallic mineral products manufacturing sector. In comparison to the level of value added generated by the working of stone subsector, this corresponded to an investment rate of 14.1%, which was significantly lower than the average rate (19.1%) recorded for other non-metallic mineral products manufacturing in 2006.

Average personnel costs of EUR 23.5 thousand per employee within the EU-27's working of stone subsector were EUR 7.1 thousand less than the average across other non-metallic mineral products manufacturing in 2006. Nevertheless, personnel costs in the subsector accounted for a much higher proportion of operating expenditure than across other non-metallic mineral products manufacturing (26.8% compared with 21.6%), underlining the relatively labour-intensive nature of working with stone.

The apparent labour productivity of the EU-27's working of stone subsector was EUR 31.5 thousand of value added per person employed in 2006, just over one third (37.5%) less than the average generated by each person employed within other non-metallic mineral products manufacturing activities. Despite relatively low personnel costs in this subsector, the wage-adjusted labour productivity ratio for the working of stone subsector (133.7%) remained lower than that for any of the other non-metallic mineral products manufacturing activities at the NACE group level and well below the average for all of these activities (164.5%).

¹³⁷Bulgaria, Cyprus, Poland and Romania, 2005; the Czech Republic, Malta and the Netherlands not available.

Manufacture of miscellaneous non-metallic mineral products

The manufacture of miscellaneous non-metallic mineral products (NACE Group 26.8) was an activity that employed 97.9 thousand persons in 2006 (6.2% of the other non-metallic mineral products manufacturing workforce) in 3.7 thousand enterprises across the EU-27. These enterprises generated EUR 5.1 billion of value added in 2005, equivalent to just over one quarter (26.0%) of the subsector's turnover. By far the largest of the two activities within this miscellaneous group was the manufacture of other non-metallic mineral products not elsewhere classified (NACE Class 28.82), which generated EUR 4.2 billion of added value in 2006 compared with EUR 1.5 billion for the production of abrasive products (NACE Class 26.81).

A little less than one third (31.1%) of the value added generated by the EU-27's miscellaneous non-metallic mineral products manufacturing subsector in 2005 came from Germany, which was about three times the size of the next largest contributions from Italy (11.0%) and the United Kingdom (10.2%). However, the relative contribution of this activity to the value added of the [non-financial business economy](#) was greatest in Slovenia (0.5%), about five times the average for the EU-27 as a whole.

The development of the EU-27's production index for miscellaneous non-metallic mineral products manufacturing was broadly similar to that for all other non-metallic mineral products manufacturing during the period between 1997 and 2007, albeit with a much steeper rise in output through from 2003. Over the ten-year period, the output of miscellaneous non-metallic mineral products rose by an average 2.5% per year.

[Tangible investment](#) in the EU-27's miscellaneous non-metallic mineral products manufacturing subsector was EUR 1.2 billion in 2006. Tangible investment within the subsector represented 7.5% of all tangible investment across the activities of other non-metallic mineral products manufacturing in 2006. The level of tangible investment in this subsector was in line with its relative contribution to the value added generated across other non-metallic mineral products manufacturing as a whole, resulting in similar rates of investment, 17.3% in 2005 compared with an average of 17.7% for other non-metallic mineral products manufacturing.

Although [personnel costs](#) of EUR 38.9 thousand per employee on average in the EU-27's miscellaneous non-metallic mineral products manufacturing subsector in 2005 were just over one quarter (27.1%) more than the average across all other non-metallic mineral products manufacturing, they represented a smaller share of operating expenditure (20.1% for the subsector compared with 23.5% across other non-metallic mineral products manufacturing in the same year).

The apparent labour productivity of the EU-27's miscellaneous non-metallic mineral products manufacturing subsector was EUR 52.3 thousand per person employed in 2005, which was 13.7% higher than the average across other non-metallic mineral products manufacturing. However, with average personnel costs being so much higher, the wage adjusted labour productivity ratio for this subsector (134.4%) in 2005 was much lower than the corresponding ratio (150.6% in 2005) for the EU-27's other non-metallic mineral products manufacturing activities.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include [short-term statistics \(STS\)](#) and the [PRODCOM](#) statistics on the production of manufactured goods.

Context

The processes of transforming mineral raw materials such as clay, lime, sand or stone into other non-metallic mineral products (for use, among others, by construction, food and beverages manufacturing, or households in the form of consumer durables) tend to be energy-intensive. Indeed, energy costs accounted for 9.5% of the purchases of goods and services in the EU's other non-metallic mineral products manufacturing sector in 2006, the second highest ratio after non-energy mining and quarrying (NACE Subsection CB) among the industrial

structural business statistics sectors. Within this sector, the share of energy costs in purchases of goods and services reached 14.9% for the EU-27's ceramic goods and clay products manufacturing subsector.

Current policy initiatives are focused on environmental impacts, energy strategies, and health and safety. Under the Competitiveness and Innovation Programme (CIP), independent consultants delivered studies to the [European Commission's Directorate-General for Enterprise and Industry](#) on the competitiveness of the ceramics and glass sectors in October 2008.

Challenges were identified, including ensuring the availability of energy and raw materials at affordable prices, the need to minimise energy waste, reduce energy use, as well as maintaining emissions within targets and removing tariff and non-tariff international barriers to trade. Suggested areas of development were a focus on the high quality and high value products end of the market, investment in cleaner technologies and environmental management systems, investment in more efficient and flexible automation technologies, improved and more targeted skills training programmes and efforts at a policy level to establish EU environmental regulations on a global platform.

Notes

Structural metal products manufacturing statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). The present article covers the manufacture of structural metal products, corresponding to [NACE Rev 1.1 Group 28.1](#), which is part of the [metals and metal products](#) sector. Structural metal products include:

- metal supports and structures;
- prefabricated buildings;
- metal doors;
- window frames;
- shutters.

The vast majority of structural metal products are destined for the construction sector (see [Construction statistics - NACE Rev. 1.1](#)). Demand is therefore closely linked to developments in the construction sector for new housing, renovation and civil engineering projects.

	Enterprises (thousand)	Turnover (EUR million)	Value added (EUR million)	Persons employed (thousand)	Share in total (%)	
					Value added	Persons employed
Structural metal products	121.7	123 086	40 839	1 116.7	100.0	100.0
Metal structures and parts of structures	55.8	88 050	28 922	742.3	70.8	66.5

Source: Eurostat (SBS)

Table 4: Manufacture of structural metal products (NACE Group 28.1). Expenditure, productivity and profitability, EU-27, 2006

Structural metal products manufacturing (NACE Group 28.1) was the core activity of 121.7 thousand enterprises in the Member States and provided employment to just over 1.1 million persons in the EU-27 or about one in every five workers (22.0%) within the metals and metal products manufacturing (NACE Subsection DJ) sector in 2006. The structural metal products manufacturing sector in the EU-27 had a turnover of EUR 123.1 billion in 2006, almost one third (33.2%) of which was retained as added value. Of the EUR 40.8 billion of value added generated by the EU-27's structural metal products sector in 2006, seven tenths (70.8%) came from the manufacture of metal structures and parts of structures subsector (NACE Class 28.11), the remainder coming from the manufacture of builders' carpentry and joinery of metal subsector (NACE Class 28.12).

Germany had the largest structural metal products manufacturing sector within the EU-27, contributing a little over one fifth (22.5%) of all the value added generated among the Member States. The second and third largest contributions were from Italy (16.4% of the EU-27's value added) and Spain (13.6%). In terms of the relative contribution of the value added generated by the structural metal products sector to the non-financial business economy, Greece was the most specialised Member State¹³⁸ in this activity, its contribution of 1.2% being about two thirds more than the EU-27 average. In these terms, Slovenia and then Italy were the next most specialised Member States in structural metals products manufacturing.

The development of the production index for structural metals products manufacturing during the ten years through to 2007 was broadly similar to that for metals and metal products manufacturing, except that the period of relatively unchanged output that started in 2000 extended beyond 2003 to 2005. Either side of this period of stability, output growth was stronger for structural metals products manufacturing than for metals and metal products as a whole, which was reflected in a faster rate of output growth for structural metal products manufacturing over the ten years through to 2007 (an average rate of growth of 2.7% per year compared with 2.1% per year).

Expenditure and productivity

Tangible investment in the EU-27's structural metal products manufacturing sector was EUR 4.2 billion in 2006, accounting for an eighth (12.5%) of all tangible investment in the activities of metals and metal products manufacturing. In comparison with value added generated, this level of tangible investment represented an investment rate of 10.2% for the EU-27's structural metal products manufacturing activities in 2006, notably less than the average investment rate (13.6%) for all metal and metal products manufacturing activities.

Average personnel costs within the EU-27's structural metal products manufacturing sector were EUR 26.3 thousand per employee in 2006, the lowest average among the dozen NACE groups that comprise metals and metal products manufacturing, and approaching one fifth lower (18.4%) than the average for metals and metal

¹³⁸Bulgaria, Cyprus, Poland and Romania, 2005; Malta and the Netherlands, not available.

products manufacturing activities. Nevertheless, personnel costs accounted for a higher proportion of [operating expenditure](#) in the structural metal products manufacturing sector than was the case across all metals and metal products manufacturing activities (23.7% compared with 19.2%), supporting the notion that this was a relatively low-cost, labour-intensive sector.

EU-27 apparent [labour productivity](#) of EUR 36.6 thousand per person employed in the structural metal products manufacturing sector was the lowest among the NACE groups within the metals and metal products manufacturing sector in 2006 and about one quarter (24.0%) less than the average for all such activities. Productivity remained relatively low, even after adjustments for low average personnel costs; the [wage-adjusted labour productivity ratio](#) for the EU-27's structural metal products manufacturing sector was 139.1% in 2006 compared with a ratio of 149.3% for all metals and metal products manufacturing activities. This was a characteristic noted across the vast majority of the Member States, exceptions being limited to Germany, Lithuania, Luxembourg and the United Kingdom.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include the [PRODCOM](#) statistics on the production of manufactured goods.

Context

The metals and metal products manufacturing sector is part of a diverse and interwoven economic network that incorporates upstream sectors and large downstream segments of manufacturing such as the transport equipment manufacturing and construction sectors. The challenges faced by the EU's metals and metal products manufacturing sector therefore have direct and indirect consequences on many other parts of the economy. Looking ahead, a Communication ([COM\(2008\) 108](#)) from the [European Commission](#) to the [Council](#) and the [European Parliament](#) on the competitiveness of the metals industries was adopted in February 2008, and highlighted the challenges to be faced.

The EU-27 is largely dependent on imports of ore and concentrates for steel, ferro-alloys and non-ferrous metals production; it produces only 1.7% of the world's nickel, 2% of its iron ore and 5% of its copper ([SEC\(2007\) 771](#)). Access to minerals and secondary raw materials at competitive prices is important, especially given the exhaustion of certain deposits in the EU-27 over time or their absence, and supply constraints that have been exacerbated by the strong growth in international demand from emerging economies such as China and India. This concern was part of a raw materials initiative of the European Commission ([COM\(2008\) 699](#)).

Parts of the metals and metal products manufacturing sector are highly [energy-intensive](#) . Energy costs for the EU-27's metals and metal products manufacturing sector accounted for 4.4% of purchases of goods and services in 2006, which was the third joint highest proportion among the industrial structural business statistics sectors, albeit well behind non-energy mining and quarrying (10.1%) and other nonmetallic mineral products (9.5%). Within this sector, however, energy costs in the casting of metals subsector accounted for 7.2% of purchases of goods and services in 2006 and in the first processing of ferrous metals as much as 7.9%. This level of energy consumption has important implications for energy and environmental (particularly climate change) policy.

The metals and metal products manufacturing sector is covered by a Directive on [integrated pollution prevention and control \(IPPC\)](#) and [REACH](#) . A proposal from the European Commission on the review of EU [Emissions trading system \(ETS\)](#) adopted in January 2008 ([COM\(2008\) 30](#)) foresees the inclusion of non-ferrous metals from 2013 onwards, along with some transitional measures to avoid 'carbon leakage'.

Notes

Telecommunication sector statistics - NACE Rev. 1.1

Data from January 2009. Most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers telecommunication sector statistics, corresponding to NACE Group 64.2, which is part of the [media and communications](#) sector. The activities covered in this article are the distribution of sound, images, data and other information via cables, broadcasting, relay or satellite. These services include:

- the management and maintenance of networks;
- the provision of services using these networks, including the provision of radio and television services, but not the production of radio and television programmes.

This article covers, for a large part, the activities of the so-called information society, a society whose wealth is based on its ability to process, store, retrieve and communicate information in whatever form – oral, written or visual. Enterprises acting in computer and related activities, such as hardware, software or data processing, are covered in [Computer and information services statistics - NACE Rev. 1.1](#).

Source: Eurostat (STS)

Figure 1: Telecommunications (NACE Group 64.2). Index of turnover, EU-27 (2000=100)

Main statistical findings

Focus on mobile and fixed line telephony

Information on the market shares of operators in fixed and mobile telecommunications in the Member States shows that incumbents (those enterprises that were active before the liberalisation of the market, generally formerly state-owned telecom operators) still dominate. Across the EU they accounted for more than half of the market in 2005, whether for local, long-distance or international calls (in terms of minutes of connection or turnover). An average for the EU-25 shows that incumbent operators accounted for 72% of local calls, some 66% of long-distance calls, and 56% of international calls. However, in some countries the dominance of the incumbent operator is less marked. For example, in Finland the incumbent accounted for less than half of the market for both long-distance calls and international calls. In some Member States, the same operators for the fixed network offer local and long-distance national and international telecommunications, while in other markets some operators specialise in particular services.

For the leading operators in mobile telecommunications data are available for 2006. Based on the number of subscriptions, leading operators in mobile telecommunications generally accounted for significantly lower market shares compared with the incumbent fixed telecommunication operators, and in a large majority of the Member States they provided less than half of all subscriptions in 2006. Slovenia and Cyprus stood out from the rest of the countries as their leading operators in mobile telecommunications accounted for 71% and 90% respectively of total mobile phone subscriptions.

Information on the cost of three types of fixed line calls for September 2006 shows that the difference in the cost between Member States is considerable. Cyprus recorded the lowest costs for local and national calls (EUR 0.22 for a 10 minute call on a weekday, including VAT) while Slovakia was the most expensive, 2.7 times as high for local calls and 5.9 times as high for national calls. Germany had the lowest cost calls to the United States (EUR 0.46), whereas the cost of such calls was 12.9 times as high in Latvia.

In June 2007 legislation was adopted on charges for using public mobile telephone networks abroad (roaming charges). In September 2008 the European Commission adopted a proposal (COM(2008) 187) to extend this from July 2009 to cover roaming charges for sending text messages and using mobile data services, and to extend the duration of the existing legislation on call charges to 2013.

Structural profile

The EU-27's telecommunication services sector (NACE Group 64.2) employed some 1.2 million persons in 2005. There were few working proprietors and unpaid family workers in this sector as practically all (98.1%) members of the workforce were paid employees. This workforce generated EUR 421.2 billion of turnover in 2005 and EUR 200 billion of value added in 2006. As such, the telecommunications sector accounted for more than half of the value added in the media and communications sector (NACE Divisions 22 and 64), but less than one quarter of the workforce, indicating a very high apparent labour productivity .

The five largest EU economies also had the largest telecommunications sectors in 2006 in terms of value added. The United Kingdom and Germany ranked first, each contributing around 18% of the EU-27's total. The same two Member States had the largest workforces, both employing just over 200.0 thousand persons in telecommu-

nications. The contribution of telecommunications services to [non-financial business economy](#) value added¹³⁹ was highest in Romania (6.6%, 2005), Cyprus (5.2%, 2005) and Greece (5.0%), although it should be noted that no recent data are available for this sector for Bulgaria or Luxembourg that are traditionally quite highly specialised in telecommunications.

Annual [short-term statistics](#) are available for the index of turnover for telecommunication services for the years 2000 to 2007. The EU-27's turnover growth was uninterrupted during this period; with growth averaging 6.1% per year, some way above the 5.3% average for non-financial services (NACE Sections G to I and Divisions 72 and 74). Growth was very constant between 2002 and 2005, before slowing in 2006 (0.9%) and accelerating again in 2007 (4.2%).

Expenditure and productivity

The EU-27's telecommunications sector recorded high [tangible investment](#), valued at EUR 46.2 billion in 2005. The [investment rate](#), showing the relation between investment and value added, was 24.3% in 2005, the highest rate among the sub-sectors of the media and communications sector, and the only one that was above the non-financial business economy average. Several Member States recorded particularly high investment rates in the telecommunications sector, most notably Romania, Cyprus (both 2005) and the United Kingdom where investment rates in this sector were more than double the national average for the non-financial business economy.

The EU-27

's telecommunications sector recorded one of the highest average [personnel costs](#) (EUR 51.5 thousand per employee) within the non-financial business economy in 2005. Despite this, total personnel costs made up just 19.9% of [operating expenditure](#) in the EU-27's telecommunications sector in 2005, the lowest share of the four media and communications sectors; this share was nevertheless still higher than the non-financial business economy average (17.1%) in the same year. Apparent [labour productivity](#) was also very high in the telecommunications sector, the EUR 159.4 thousand of value added per person employed was the fourth highest among the non-financial business economy NACE groups in 2005 or 2006, and the highest of all of the non-financial services NACE groups. Despite these high average personnel costs, the telecommunications sector recorded a [wage-adjusted labour productivity ratio](#) of 309.4%, indicating that apparent labour productivity covered average personnel costs three times over. This was the fifth highest level of this ratio among the non-financial business economy NACE groups for which data are available. Without exception every Member State (with data available in 2005 or 2006) recorded a wage-adjusted labour productivity ratio that was higher for the telecommunications sector than for the non-financial business economy as a whole.

Data sources and availability

Data sources include [short-term statistics \(STS\)](#) and Eurostat information society statistics.

Context

This sector gathers together several activities linked to media and communication activities, however, within this group a distinction has to be made between traditional activities (for example, [postal services](#)) for which the level of activity is rather stable and other newer activities (such as mobile telephony and electronic publishing), for which growth developments are more marked.

As part of the initiatives to support the development of the information society, the [European Commission](#) launched the [i2010 strategy](#) in June 2005, a digitally-led strategy for growth and jobs and the EU's policy strategy to boost the digital economy. Its aims are to: establish a European information space, in other words, a true single market for the digital economy so as to exploit fully the economies of scale offered by Europe's consumer market; reinforce innovation and investment in [information and communication technology \(ICT\)](#) research given that ICTs are a principle driver of the economy; and promote inclusion, public services and

¹³⁹Cyprus and Romania, 2005; Bulgaria, the Czech Republic, Ireland, Luxembourg, Malta, the Netherlands, Poland and Slovenia, not available.

quality of life, in other words, extending the European values of inclusion and quality of life to the information society. In April 2008, the results of a mid-term review of i2010 ([COM\(2008\) 199](#)) was published. A few examples of the activities cited in the review include a new regulatory framework for audiovisual media services, legislation to create a single market for mobile phone use across borders, and proposals to reform the regulation of telecommunications. Concerning the last of these examples, in November 2007 the Commission adopted proposals for a reform of the regulatory framework for telecommunications with the aim to provide consumers with better and cheaper communication services, whether for mobile phones, Internet or cable TV. The proposals covered strengthening consumer rights; reinforcing competition; promoting investment in infrastructure (freeing radio spectrum for wireless broadband services); and making networks more reliable and more secure. Following discussions in the [European Parliament](#) and the [Council](#) a revised set of proposals were adopted by the Commission in November 2008.

Table 4b: Key indicators, telecommunications (NACE Division 61), 2009 - Source: Eurostat (sbs_na_1a_se_r2)

Main statistical findings

Structural profile

There were around 40 thousand enterprises operating within the telecommunications services (Division 61) sector in the EU-27 in 2009. Together they employed 1.2 million persons, equivalent to 0.9% of the non-financial business economy (Sections B to J and L to N and Division 95) workforce, or in excess of one in five (20.9%) of those employed in information and communication services (Section J). The EU-27 telecommunications services sector generated EUR 180 000 million of value added in 2009 which was 3.2% of the non-financial business economy total and well in excess of one third (37.7%) of the information and communication services total.

As such, with a considerably higher share of value added than employment, the telecommunications services sector had apparent labour productivity that was well above average. EU-27 productivity (using this measure) was EUR 150 thousand of value added per person employed in 2009, which was 3.6 times as high as the non-financial business economy average of EUR 41.6 thousand per person employed and almost double the information and communication services average of EUR 83 thousand per person employed. When ranking all of the NACE divisions within the non-financial business economy, telecommunications services had the fourth highest level of apparent labour productivity in 2009.

Average personnel costs for the EU-27 telecommunications services sector were, at EUR 50 thousand per employee, less elevated than apparent labour productivity – some two thirds higher than the non-financial business economy average of EUR 30.0 thousand per employee. Average personnel costs per employee for the telecommunications services sector were only EUR 1.4 thousand per employee higher than the average for the whole of information and communication services.

As a result, the wage-adjusted labour productivity ratio (which combines the two previous indicators and shows the extent to which value added per person employed covers average personnel costs per employee) stood at 294.6% for the EU-27 telecommunications services sector in 2009. This was the fifth highest level of wage-adjusted labour productivity among the NACE divisions that compose the non-financial business economy and well above the information and communication services average of 171.2% or the non-financial business economy average of 138.8%.

The gross operating rate (the relation between the gross operating surplus and turnover) is one measure of operating profitability; it stood at 29.7% for the EU-27's telecommunications services sector in 2009, which was just over three times as high as the non-financial business economy average (9.7%) and some 8.8 percentage points above the information and communication services average (20.9%). As such, the telecommunication services sector recorded the sixth highest level of profitability (using this measure) among the NACE divisions

within the non-financial business economy.

Sectoral analysis

More than half of all the enterprises that were active within the EU-27's telecommunications services sector in 2009 were classified in the residual grouping of other telecommunications activities (Group61.9), some 21700 enterprises or 54.9% of the telecommunications services total. The next largest subsector (in terms of numbers of enterprises) was that of wired telecommunications activities (Group61.1), for which there were 11200 enterprises across the EU-27 in 2009. This was more than double the number of enterprises whose principal activity was wireless telecommunications (4700, Group61.2), while there were very few enterprises operating satellite telecommunications activities (800, Group61.3).

The relative weight of these four subsectors was somewhat different in terms of employment. Wired telecommunications activities were the main employer, with an EU-27 workforce of 569.3 thousand persons in 2009 (49.7% of the telecommunications services total). More than one quarter of the telecommunications services workforce worked in other telecommunications activities, while just over one in six was employed within wireless telecommunications activities.

Wireless telecommunications activities had a far higher share of value added, accounting for 30.0% of the added value within the EU-27's telecommunications services sector in 2009. This was still well behind the value added generated by wired telecommunications activities (45.9% of the sectoral total or EUR82650 million). The relative weight of other telecommunications activities was considerably lower in terms of value added, accounting for 22.1% of the sectoral total for telecommunications services, while satellite telecommunications activities accounted for a small share (1.6% in 2008).

The EU-27 recorded apparent labour productivity in excess of EUR100 thousand per person employed in all four subsectors. Note the data for satellite telecommunication activities are only available for 2008, when EUR316 thousand of added value was generated per person employed. Wireless telecommunications activities had the next highest level of apparent labour productivity, EUR265 thousand per person employed in 2009, while the ratio for wired telecommunications activities was EUR139 thousand per person employed (also in 2009).

There was a high degree of similarity regarding average personnel costs across the EU-27 telecommunications services subsectors in 2009. For wired, wireless and satellite telecommunications activities average personnel costs ranged between EUR50.6 thousand and EUR50.0 thousand per employee, while those for other telecommunications activities were only slightly lower, at EUR48.4 thousand per employee.

As such, with little difference in average personnel costs, the ranking of subsectors according to their wage-adjusted labour productivity ratios was highly influenced by apparent labour productivity figures. EU-27 wireless and satellite telecommunications activities had very high wage-adjusted labour productivity ratios, at 523.6% and 522.8% respectively; the latter for 2008. As such, wireless telecommunications activities recorded the fifth highest wage-adjusted labour productivity ratio among the NACE groups that make-up the non-financial business economy in 2009. The wage-adjusted labour productivity ratio for wired telecommunications activities (275.8%) meant that it ranked just outside the top ten NACE groups in the non-financial business economy, lying in eleventh place in 2009.

The EU-27's telecommunications services subsectors also consistently recorded high gross operating rates. These peaked in 2009 at 32.1% for wired telecommunications activities, just 0.1 percentage points above the rate that was registered for wireless telecommunications activities. As such, both of these subsectors were among the top ten NACE groups in the non-financial business economy with the highest levels of profitability (using this measure).

Country analysis

The United Kingdom had the highest share (16.9%) of EU-27 value added within the telecommunications services sector in 2009, in large part due to a 72.7% share of the added value generated within the EU-27's other telecommunications activities subsector. Indeed, France recorded the highest share of EU-27 value added for the other three subsectors, with a 21.6% share of wireless telecommunication activities and a 17.6% share of

wired telecommunication activities (a full set of information is not available for the relatively small activity of satellite telecommunications services).

The highest contribution made by the telecommunications services sector to the non-financial business economy in value added terms was observed in Bulgaria, where this sector contributed 5.9% of total added value in 2009. This reflected a general pattern of relatively high shares for the majority of the Member States that joined the EU in 2004 or 2007, as the next highest shares were recorded in Slovakia, Romania, Estonia and Latvia. The telecommunications services sector provided at least 4.5% of non-financial business economy value added in each of these four countries in 2009.

The highest apparent labour productivity within the Member States for the telecommunications services sector in 2009 was recorded for Spain (EUR271 thousand per person employed). This figure was almost seven times as high as the Spanish average for the whole of its non-financial business economy. In Portugal, the apparent labour productivity of the telecommunications sector was 9.1 times as high as the national non-financial business economy average, at EUR214.5 thousand per person employed. Compared with national non-financial business economy, the Irish telecommunications services sector recorded apparent labour productivity that was double its average. Nevertheless, based upon this comparison this was the lowest ratio among the Member States, indicating how high the apparent labour productivity in this sector is when compared with other activities.

The wage-adjusted labour productivity ratio peaked in 2009 in Bulgaria at 533.7%, followed by Spain (460.6%) and the Czech Republic (435.9%). These values were considerably higher than the respective national averages recorded for the whole of the non-financial business economy. Indeed, in Spain the wage-adjusted labour productivity ratio in this sector was 3.5 times as high as the non-financial business economy average, and in Italy it stood 3.4 times as high, while for Bulgaria and for Lithuania (361.5%) the wage-adjusted labour productivity ratio in this sector was higher than in any other NACE division within the non-financial business economy in 2009, as it also was in Croatia (370.7%). The lowest wage-adjusted labour productivity ratio for the telecommunications services sector was recorded in Cyprus (213.7%), where the wage-adjusted labour productivity ratio was nevertheless 35% higher than the non-financial business economy average.

A similar pattern was observed for the gross operating rate, as comparatively high rates were consistently recorded across all of the Member States. These peaked in 2009 at 41.9% for the Bulgarian telecommunications services sector, followed by 39.3% in the Czech Republic which was the highest gross operating rate in any NACE division within the Czech non-financial business economy. The lowest gross operating ratio in this sector was recorded in Slovenia (21.0%), although this figure was almost three times as high as the Slovenian non-financial business economy average.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the telecommunications services sector in the EU, as covered by NACE Rev.2 Division61. This division includes the activities of providing telecommunications and related service activities, such as transmitting voice, data, text, sound and video. The transmission facilities that carry out these activities may be based on a single technology or a combination of technologies. The commonality of activities classified in this division is the transmission of content, without being involved in its creation. The breakdown in this division is based on the type of infrastructure that is being operated. In the case of the transmission of television signals this may include the bundling of complete programming channels (produced by units classified to Division60, programming and broadcasting activities) in to programme packages for distribution.

Wired, wireless and satellite telecommunications activities include operating and maintaining switching and transmission facilities to provide communications; these activities also include the provision of internet access.

For wired technology, telecommunications are provided point to point via landlines, microwave, or a combination of landlines and satellite linkups; operating of cable distribution systems (for example, the distribution of data and television signals); furnishing telegraph and other non-vocal communications using own facilities. For wireless telecommunications omni-directional transmission via airwaves is provided and these services may be based on a single technology or a combination of technologies. Activities of maintaining and operating paging as well as cellular and other wireless telecommunications networks are also included. Satellite telecommunications activities use satellite infrastructure: this includes the delivery of visual, aural or textual programming received from television channels, television stations and networks, or radio networks to consumers via direct-to-home satellite systems.

Other telecommunications activities include the provision of specialised telecommunications applications, such as satellite tracking, communications telemetry, and radar station operations, as well as the operation of satellite terminal stations and associated facilities operationally connected with one or more terrestrial communications systems and capable of transmitting telecommunications to or receiving telecommunications from satellite systems. The provision of internet access over networks between the client and the ISP not owned or controlled by the ISP, such as dial-up internet access are included, as well as the provision of telephone and internet access in facilities open to the public, voice over internet protocol provision and telecommunications resellers (in other words, purchasing and reselling network capacity without providing additional services).

This NACE division is composed of four groups:

- wired telecommunications activities (Group61.1);
- wireless telecommunications activities (Group61.2);
- satellite telecommunications activities (Group61.3);
- other telecommunications activities (Group61.9).

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). The present article covers the manufacture of textiles, corresponding to [NACE Rev 1.1 Division 17](#), which is part of the [textiles, clothing, leather and shoe production](#) sector. The manufacture of textiles includes such processes as:

- spinning;
- weaving;
- the finishing of products.

	Enterprises (thousand)	Turnover (EUR million)	Value added (EUR million)	Persons employed (thousand)	Share in total (%)

Source: Eurostat (585)

Table 4: Manufacture of textiles (NACE Division 17). Main indicators, 2006 (1).

There were 79.1 thousand enterprises across the EU-27 for which the manufacture of textiles (NACE Division 17) was their main activity in 2006. These enterprises employed just over one million people, a little over one third (35.4%) of the textiles, clothing and leather manufacturing workforce. They generated an estimated EUR 30.0 billion of value added in 2006, closer to one half (46.3%) of the added value generated across textiles, clothing and leather manufacturing.

The largest activity within the textiles sector was the manufacture of other textiles (NACE Group 17.5) such as carpets, rugs and non-woven articles; this subsector generated an estimated EUR 8.0 billion of value added across the EU-27 in 2005. The activity of textile weaving (NACE Group 17.2) generated EUR 5.4 billion of value added, making it the next largest. By far the smallest activity was the manufacture of knitted and crocheted fabrics (NACE Group 17.6), which generated EUR 1.2 billion of value added.

The principal textile manufacturing Member State was Italy, with EUR 8.7 billion of value added generated in 2006 accounting for around 28.9% of EU-27 value added. The textiles manufacturing sectors in Germany, the United Kingdom and France were the next largest, together contributing just over a third (36.0%) of the EU-27's value added. All three countries were relatively unspecialised in textile manufacturing, however, as the relative contribution of this sector to national non-financial business economy value added was beneath the EU-27 average. In contrast, Portugal, Bulgaria (2005) and Italy were relatively specialised in the manufacture of textiles, as this sector contributed about 1.5% of the total value added in their respective non-financial business economies in 2006, between two and a half and three times the EU-27 average.

The production index of the EU-27's textiles manufacturing activity declined by an average 2.8% per year in the ten years through until 2007, despite a temporary upturn in 2000 and a marked slowdown in the rate at which output fell in 2006 and 2007. This pattern of development was common to six of the seven textile manufacturing NACE groups, with the sharpest rate of decline (an average -5.6% per year) being recorded for the preparation and spinning of textile fibres (NACE Group 17.1). The exception was the manufacture of other textiles (NACE Group 17.5) such as carpets, rugs and non-woven articles, for which the production level in 2007 was remarkably similar to that in 1997 and was relatively stable in the period in-between.

Expenditure and productivity

A little over three fifths (61.3%) of the tangible investment within the textiles, clothing and leather manufacturing sector was for textiles manufacturing in 2006. The investment rate, defined as the ratio of tangible investment to value added, was 15.0% for textiles manufacturing, which was considerably higher than the rates for clothing or leather manufacturing.

The structure of [operating expenditure](#) for the EU-27's textiles manufacturing sector was broadly similar to that of textiles, clothing and leather manufacturing as a whole, although [personnel costs](#) accounted for a slightly higher share within the textiles sector (23.0% in 2005). This higher share was, in part, due to the higher – albeit still relatively low – average personnel costs; average personnel costs within the EU-27's textiles manufacturing sector were EUR 21.5 thousand per employee, almost one third (33.0%) more than the average across textiles, clothing and leather manufacturing in 2006.

The apparent [labour productivity](#) of the EU-27's textiles manufacturing sector in 2006 was EUR 28.3 thousand per person employed, which was also almost one third (31.0%) more than the corresponding productivity level across textiles, clothing and leather manufacturing as a whole. Adjusting productivity for the differences in average personnel costs, the resulting [wage-adjusted labour productivity ratio](#) of the textiles manufacturing sector (131.5%) was very similar to the average ratio across textiles, clothing and leather manufacturing as a whole (133.6%). Bulgaria recorded a particularly high wage adjusted labour productivity ratio for textiles manufacturing (198.2%) relative to its average ratio for textiles, clothing and leather manufacturing (145.4%). Across all of the Member States¹⁴⁰, however, the wage adjusted labour productivity ratios for the textiles manufacturing sector were lower than the corresponding ratios for the non-financial business economy.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include the [PRODCOM](#) statistics on the production of manufactured goods.

Context

Since the closure of the [World Trade Organization's \(WTO\)](#) (ten-year, transitional Agreement on Textiles and Clothing (ATC) at the end of 2004, the European Union market for textiles, clothing, leather and footwear has been open to far more global competition, particularly from China and other Far Eastern countries. The [European Commission](#) published a study on the competitiveness, economic situation and location of production in the [textiles and clothing, footwear, leather \(and furniture\) industries](#) in 2007, which put forward some ideas for consideration: to upgrade knowledge and skills within the sector; to enhance the value added of EU manufactured products, perhaps through emphasising social ethics, environmental and health considerations and ethical sourcing; to enhance the protection of intellectual property; to foster trade and eliminate trade barriers; to improve the integration of fashion and design in the sector and better support young designers.

Table 7: Tanning and dressing of leather; manufacture of luggage, handbags, saddlery, harness and footwear (NACE Division 19). Main indicators, 2006 (1).

There were just over 267.0 thousand enterprises in the Member States for which the manufacture of textiles, clothing and leather (NACE Subsections DB and DC) was their main activity in 2006. In relative terms, this sector of the economy was larger in terms of employment than in terms of its value added generated; about 3.0 million people were employed in the sector, corresponding to 2.3% of the EU-27's non-financial business economy (NACE Sections C to I and K) workforce, whereas the EUR 64.7 billion of value added corresponded to 1.1% of the total value added generated across the non-financial business economy in 2006.

The largest activity within the sector (at NACE Division level) was the manufacture of textiles (NACE Division 17), which accounted for a little under one half (46.3%) of sectoral value added in 2006. Just over one third

(34.7%) of value added was generated by the EU-27's manufacture of clothing (as defined by the activities in NACE Division 18), with the remainder (18.4%) being generated by leather manufacturing (NACE Division 19).

Italy was the principal textiles, clothing and leather manufacturing Member State, generating EUR 21.8 billion of value added, which was the equivalent of one third (33.6%) of EU-27 value added in this sector in 2006. The other main textiles, clothing and leather manufacturing Member States within the EU-27 were Germany (accounting for 12.1% of the EU-27's value added), France (11.6%), Spain (9.2%) and the United Kingdom (7.8%). Of these five Member States, only Italy was specialised in the manufacture of textiles, clothing and leather; as this sector contributed 3.4% of the value added generated in its non-financial business economy, three times the average contribution recorded across the EU-27 in 2006. However, this measure of specialisation was even stronger in Romania and Bulgaria. In Romania, the textiles, clothing and leather manufacturing sector contributed 5.3% to the value added generated across its non-financial business economy in 2005; in Bulgaria this proportion was 4.7%.

This relative specialisation was also clear in terms of employment. There were a number of regions in Romania where between 8% and 15% of the non-financial business economy workforce were employed in the textiles, clothing and leather manufacturing sector. The most specialised region (at the level of detail shown in the map) was Norte in Portugal, however, where about one in every five (18.3%) persons employed in the non-financial business economy worked in textiles, clothing and leather manufacturing. There was also high specialisation of textiles, clothing and leather manufacturing in many regions of Italy, as well as across Slovenia, Estonia, Lithuania and Bulgaria (which are each considered as a single region at the level of detail in the map).

There was a strong downward trend in the index of [production](#) for textiles, clothing and leather manufacturing for the EU-27

during the period between 1997 and 2007, at a time when there was a relatively steady rise in total industrial output. Textiles, clothing and leather manufacturing output declined by one third in the ten years through to 2007, at an average rate of 4.0% per year, although the falls in 2006 (-1.3%) and 2007 (-0.6%) were much more moderate than this longer-term trend. This output pattern was also reflected in the production indices of each of the three main types of manufacturing. However, the declines noted for leather manufacturing (an average -5.4% per year over the ten years through until 2007) and clothing (an average -5.3% per year) were almost twice as strong as for textile manufacturing (an average -2.8% per year).

[Small and medium-sized enterprises](#) (SMEs, enterprises employing less than 250 people) dominated the textiles, clothing and leather manufacturing sector in the EU-27, accounting for around three quarters of sectoral value added (74.5%) and employment (75.3%) in 2006. This size structure set the sector apart from most industrial activities in the EU-27, as across the EU-27's industrial economy (NACE Sections C to E) as a whole SMEs generated less than half (42.5%) of total value added. The share of value added generated by SMEs in the textiles, clothing and leather manufacturing sector was also significantly higher than the average (57.9%) across the non-financial business economy.

Across industry and the non-financial business economy, the apparent [productivity of labour](#) tended to rise through the size classes, suggesting economies of scale. In contrast, there was almost no distinction between the apparent labour productivity levels of the size classes within the textiles, clothing and leather manufacturing sector. Indeed, across all size classes within the sector, the apparent labour productivity level was low (between EUR 17.0 thousand and EUR 23.0 thousand per person employed) and about one half of the average across the EU-27's non-financial business economy (EUR 44.0 thousand per person employed).

Employment characteristics

The textiles and clothing manufacturing subsector and the leather manufacturing subsector were the only industrial subsections that employed more women than men across the EU-27 in 2007. Indeed, women accounted for a little more than two thirds (69.4%) of the textiles, clothing and leather manufacturing workforce as a whole, which was about twice the average share (35.1%) across the EU-27's non financial business economy and even more than the industrial average (30.1%). With the exception of Belgium and the Netherlands among the Member States for which data are available¹⁴¹, women provided a majority of the workforce within the sector. In the [Baltic Member States](#), Bulgaria, Hungary and Romania, women represented between eight and nine in every ten workers in the textiles, clothing and leather manufacturing sector.

¹⁴¹Luxembourg and Malta, not available.

Given the high proportion of women employed in the textiles, clothing and leather manufacturing sector of the EU-27, it is perhaps surprising that the proportion of workers engaged on a part-time basis was as low as 8.2% in 2007, as it is often a characteristic that activities with a high proportion of women in the workforce are associated with high part-time employment rates. Indeed, part-time workers in the textiles, clothing and leather manufacturing sector were much less common than across the non-financial business economy, where they represented 14.3% of the workforce.

Another key feature of the workforce was that the proportion of those aged under 30 in the EU-27's textiles, clothing and leather manufacturing sector (18.4%) was much lower than the average across the non-financial business economy (24.3%) in 2007. The relative difference between the two was made up for in workers aged between 30 and 49 years of age, the proportions of those workers aged 50 years or over being almost identical. The relative absence of young workers in the textiles, clothing and leather manufacturing sector was most acute in Greece, Latvia and the Netherlands, where they represented about a third of the equivalent share of workers aged under 30 across their respective non-financial business economies. Other countries where this characteristic was particularly pronounced included Slovenia, Estonia, Poland and Austria. Indeed, among those Member States for whom data are available¹⁴², it was only in Romania that the share of young workers in this sector was higher than that across its non-financial business economy in 2007. In contrast, the proportion of workers in the textiles, clothing and leather manufacturing sector aged 50 or over was particularly high in Cyprus (63.6%), especially when compared against the average (25.2%) across the whole of its non-financial business economy.

Expenditure, productivity and profitability

The level of **tangible investment** in the textiles, clothing and leather manufacturing sector was EUR 7.3 billion in 2006, accounting for just 0.7% of investment across the EU-27's non-financial business economy. This relative level of investment was lower than the sector's relative contribution (1.1%) to value added within the non-financial business economy in 2006, a characteristic that was common across the Member States but particularly notable in some of the key textile, clothing and leather manufacturing Member States like Italy, Bulgaria and Romania. The **investment rate** across the EU-27's textiles, clothing and leather manufacturing sector was 11.3% in 2006, considerably lower than the average rate for the non-financial business economy (18.4%). Investment rates for the clothing and leather subsectors were particularly low (7.9% and 8.9% respectively).

The average annual **cost of personnel** within the EU-27's textile, clothing and leather manufacturing sector was EUR 16.2 thousand per employee in 2006, which is very low and a little more than two fifths (43.9%) less than the average across the non-financial business economy. This characteristic was apparent in all of the Member States for which data are available¹⁴³, with the exception of Luxembourg where average personnel costs in this sector were above their respective national averages for the non-financial business economy.

Despite relatively low average personnel costs, the proportion of **operating expenditure** accounted for by personnel costs (20.5%) was notably higher than the share across the EU-27's non-financial business economy (16.1%). These figures support the notion of a low-wage, labour-intensive manufacturing sector.

The apparent **labour productivity** of those working in the EU-27's textiles, clothing and leather manufacturing sector was EUR 21.6 thousand per person employed in 2006. This was almost exactly one half of the average productivity level of all those working across the non-financial business economy, and is very low compared with other sectoral aggregates. This low productivity was all the more notable given the small proportion of part-time employment within the sector. Even after adjusting productivity levels for low average personnel costs, the resulting wage adjusted productivity ratio for the EU-27's textiles, clothing and leather manufacturing sector (133.6%) remained well beneath that (151.1%) of the non-financial business economy in 2006. The wage adjusted labour productivity ratios for each of the three subsectors (separately textiles, clothing and leather manufacturing) were very similar, with the value added per person employed being between 31% and 37% higher than the respective average personnel costs per employee.

Among the Member States, the **wage-adjusted labour productivity ratio** of the textiles, clothing and leather

¹⁴²Denmark, Ireland, Cyprus, Luxembourg, Malta and Finland, not available.

¹⁴³Bulgaria, Cyprus, Austria, Poland, Romania and Slovenia, 2005; Denmark, Ireland, Latvia, Malta, the Netherlands, Portugal and Slovakia, not available.

manufacturing sector was significantly below the national non-financial business economy average¹⁴⁴, with the exceptions of Luxembourg (where it was about two thirds higher than the non-financial business economy average) and Italy (where it was almost the same).

The **gross operating rate** of the EU-27's textiles, clothing and leather manufacturing sector was 8.6% in 2006, with very similar rates for its three subsectors. As such, this measure of profitability was notably lower than that for the non-financial business economy (10.8%) as a whole. There were a few Member States, however, where the gross operating rate for the textiles, clothing and leather manufacturing sector was higher than the average for the non-financial business economy; these were Bulgaria (2005), Hungary, Finland, and particularly Luxembourg (where it was more than double the average).

External trade

Almost three quarters (72.0%) of the value of Member States' export trade in textiles, clothing and leather goods (CPA Subsections DB and DC) was within the European Union (so-called **intra-EU** trade). The remaining share was **exports** to non-member countries (so-called **extra-EU** trade) and was valued at EUR 48.2 billion in 2007. Although this represented a fourth successive year of extra-EU export growth, this level was dwarfed by the value of EU-27 **imports**. In the first three years after the ending of the Agreement on Textiles and Clothing and its textile quotas on 31 December 2004, the value of EU-27 imports of textiles, clothing and leather goods had grown by 27.4% to EUR 102.6 billion, representing 7.7% of the value of all industrial imports in 2007. These developments resulted in a further widening of the **trade deficit** in textiles, clothing and leather goods from the EUR 38.7 billion recorded in 2004 to the EUR 54.5 billion recorded in 2007.

Exports of textiles, clothing and leather goods from the EU-27 accounted for 4.1% of all industrial exports. There was strong export specialisation in textiles, clothing and leather goods in Italy, Portugal, Bulgaria and, particularly, Romania (where they accounted for 18.8% of industrial exports). Each of these Member States, as well as Belgium and Lithuania, recorded a trade surplus in these goods in 2007. By far the largest of these trade surpluses was recorded for Italy (EUR 16.7 billion), although this has been steadily eroded over a number of years: by way of example, down from EUR 23.1 billion in 2001. In contrast, the United Kingdom had a trade deficit that widened to EUR 19.5 billion in 2007, by far the largest deficit in these goods among the Member States.

With the removal of quotas, there was a surge of imports from developing countries during 2005, particularly from China. Just under two fifths (38.7%) of the EU-27's imports of textiles, clothing and leather goods as a whole came from China in 2007. In more detail, the transitional quantitative limitations on textile and clothing products imports agreed separately between the EU and China limited the growth of imports from China in 2006 and 2007. Nevertheless, the value of textile and clothing imports (CPA Subsection DB) grew by a further 13.0% in 2007 to EUR 29.2 billion, representing more than a third (36.2%) of all EU-27 textile and clothing imports. Imports from Turkey also grew relatively strongly (up 6.5%) to EUR 12.7 billion, the equivalent of 15.8% of EU-27 imports.

In 2006, two anti-dumping investigations were launched by the **European Commission** regarding footwear, one concerning China and the other Vietnam. The punitive duties that resulted have not stopped the growth in imports from China, their value rising by 7.7% to EUR 10.6 billion in 2007, although there was considerably lower growth (up 0.7%) from Vietnam. As a result of these latest developments, China inched closer to being the origin of one half (47.9%) of all the EU-27's imports of leather and leather products in 2007, Vietnam's share falling slightly to about one tenth (10.6%).

Data sources and availability

The main part of the analysis in this article is derived from **structural business statistics (SBS)**, including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include **short-term statistics (STS)**, the **Labour force survey (LFS)** and the **COMEXT**

database for external trade.

Context

Since the closure of the [World Trade Organization's \(WTO\)](#) ten-year, transitional Agreement on Textiles and Clothing (ATC) at the end of 2004, the European Union market for textiles, clothing, leather and footwear has been open to far more global competition, particularly from China and other Far Eastern countries. The European Commission published a study on the competitiveness, economic situation and location of production in the [textiles and clothing, footwear, leather \(and furniture\) industries](#) in 2007, which put forward some ideas for consideration: to upgrade knowledge and skills within the sector; to enhance the value added of EU manufactured products, perhaps through emphasising social ethics, environmental and health considerations and ethical sourcing; to enhance the protection of intellectual property; to foster trade and eliminate trade barriers; to improve the integration of fashion and design in the sector and better support young designers.

Main statistical findings

Short-term business statistics

Industrial output in 2011 in South Africa, Australia, the EU27 and the United States had not returned to the pre-crisis levels

The line graphs presented in Figures 1 to 3 illustrate developments for industrial output, industrial output prices and retail trade sales using key short-term business statistics. The statistics presented here are annual indices but the underlying series are normally monthly or quarterly data which facilitate a rapid assessment of the economic climate. These short-term statistics show developments over time and so may be used to calculate rates of change.

The impact of the global financial and economic crisis on industrial activities and the subsequent recovery can be clearly seen for the two industrial indicators in Figures 1 and 2. In the years leading up to the recent crisis there was growth in industrial output in the vast majority of G20 members – note that the [industrial production index](#) is a volume index and so has been adjusted to remove price changes. From the second half of 2007 many economies started to experience a contraction in output alongside an acceleration of price growth. Already in 2008 the annual rates of change in the industrial production index turned negative for some G20 members, notably Japan, the United States and the EU27. In 2009 most of the other G20 members (note that no data are available for Argentina, China or Saudi Arabia) also reported negative rates of change for industrial production, the most notable exception being India (6.6% growth), while industrial output remained relatively unchanged in Indonesia and South Korea. By 2010 the annual rates of change had turned positive for all G20 members, although they turned negative again in Japan in 2011 in part as a consequence of the tsunami in March 2011.

The crisis was remarkable not just for its global scale, but also for the depth of the downturn, particularly in industrial activities. In 2009 industrial output fell by more than 10% in Turkey, South Africa and the EU27 and as much as 21.3% in Japan.

As well as clearly illustrating the impact of the financial and economic crisis, Figure 1 shows the contrasting developments of industrial activity among the G20 members in recent years as all three parts are shown with the same scale and each include the time series for the EU27. Rapid industrial growth can be seen in India and South Korea, and to a somewhat lesser extent in Turkey, Indonesia, Russia and Brazil. By contrast, industrial output in 2011 in South Africa, Australia, the EU27 and the United States was approximately the same as it had been in 2005; in other words, by 2011 output had not returned to the pre-crisis levels of 2007 and/or 2008.

As already noted, the growth rate in industrial output prices accelerated in the period leading up to the financial

and economic crisis, as prices rose in 2008 by more than 10% in Turkey, Brazil, South Africa and Argentina and by more than 20% in Russia and Indonesia. Often the rapid increase in prices reflected the rising cost of energy, food and other natural resources, as increased demand from developing countries outstripped supply. In 2009 many G20 members recorded an abrupt fall in output prices, although there were rises in Argentina, Mexico, India and Turkey in 2009 that were more modest than those experienced in 2008. The largest falls in output prices in 2009 were recorded in the United States, Russia, Australia and Japan, where industrial output prices fell more than 5%. By 2010 all G20 members, except for Japan, recorded rising industrial output prices which continued into 2011.

Over the period from 2005 to 2011 industrial output prices nearly doubled in Argentina, equivalent to an annual growth rate of 12.0%. Russia (11.4%) and Indonesia (10.6%) also averaged double-digit price increases during the period shown in Figure 2. Despite falling prices in 2009, EU27 industrial output prices increased by 3.1% per year on average between 2005 and 2011, while Japanese industrial output prices averaged increases of just 0.8% per annum.

The volume of retail sales index reflects developments once price changes have been removed; retail sales indices have particular importance as they can be used as short-term approximations for final domestic demand by [households](#). From Figure 3 it can be clearly seen that the financial and economic crisis also had an impact on [retail trade](#) output, although a much less profound one than on industrial output. The volume of retail sales fell in 2008 by 5.0% in the United States and by a more modest 0.8% in the [17 member euro area](#) (the index was unchanged in the EU27). In 2009 many G20 members recorded a fall for their volume of retail sales, most notably -7.6% in the United States and -5.0% in Russia; among the G20 members with data available, only Brazil, Australia and South Korea continued to record an increase in their volume of retail sales in 2009. By 2010 this index had returned to an upward path in all G20 members shown in Figure 3 and by 2011, the volume of sales index had returned above pre-crisis levels in all G20 members except for the EU27 and the United States.

Structural business statistics

Machinery manufacturing was one of the three largest manufacturing activities in Japan, the EU27 and the United States

Structural business statistics provide a snapshot of the business economy for a particular year, mainly focused on the level of inputs (such as labour and goods and services) and the level of output, in particular value added; data are often available at a very detailed level, for several hundred industrial, construction and services activities. The analysis presented in Tables 1 and 2 focuses on manufacturing divisions: for the EU-27 the dataset used was composed of the 24 manufacturing divisions of the [NACE Rev. 2 classification](#) (for the purpose of analysis in Table 1 the divisions for food and beverages have been aggregated), while for the other G20 members the [ISIC Rev.3 classification](#) was used which has 23 manufacturing divisions.

With the exception of South Korea, food and beverages manufacturing was one of the three largest manufacturing divisions (in value added terms) in all G20 members (see Table 1), and in several G20 members it was the largest of all manufacturing activities. The manufacture of basic metals, chemicals and motor vehicles as well as fuel processing (mainly refining and coking) were also activities that frequently figured in the top three manufacturing divisions. Somewhat less common was machinery manufacturing which was one of the three largest manufacturing activities in Japan, the EU27 and the United States, while metal products manufacturing figured in third place in the EU27 and the manufacture of radio, television and communication equipment was the largest manufacturing division in South Korea. The cumulative share of manufacturing valued added generated by the three largest manufacturing divisions ranged from 31% in Canada and Turkey to 55% in Mexico.

The most specialised G20 member for a particular manufacturing activity is the one where that activity's share in the [non-financial business economy](#) is highest, regardless of the size of the economy or the activity concerned. There are many reasons why a country or region specialises in a particular activity; these are varied and include the availability of natural resources (for example, for mineral and forest-based manufacturing), the availability of skilled employees, costs, infrastructure, legislation and the proximity to markets. Table 2 shows which G20 country outside of the EU-27 was the most specialised for each of the manufacturing divisions and compares the share of that activity in total manufacturing value added in the most specialised G20 country with the share for the EU-27. Compared with the most specialised G20 countries, the EU-27 was relatively specialised in publishing, printing and reproduction of recorded media and fabricated metal products, while it

was relatively unspecialised in fuel processing, the manufacture of tobacco products and the manufacture of radio, television and communication equipment.

Tourism

The EU27's share of worldwide tourist arrivals dropped between 1990 and 2011 from 52.9% to 39.2%

In 2011 there were around 983 million international tourist arrivals worldwide, among which 385 million were in the EU27. The number of international tourist arrivals in the EU27 increased by 155 million between 1990 and 2011, but the EU27's share of worldwide tourist arrivals dropped from 52.9% to 39.2% over the same period. It should be noted that the EU27 total includes arrivals in EU Member States of international tourists from other EU Member States; approximately 70% of arrivals in EU27 Member States in 2010 came from other EU Member States – an extended analysis is provided in Figure 5.

The growth of the tourism sector has been crucial for many countries, offering employment opportunities and a considerable revenue stream; this is particularly true for a number of developing economies which have been transformed by a vibrant tourism industry. Note that tourism statistics cover business travellers and those who travel for leisure. Equally, it is important to bear in mind that international tourists are classified according to their country of residence, not according to their citizenship. As such, citizens residing abroad who return to their country of citizenship on a temporary visit are included as international tourists.

From Table 3 it can be seen that international tourists from the United States spent considerably less abroad (EUR 56.8 billion) in 2011 than international tourists spent in the United States (EUR 83.5 billion). A similar surplus of receipts over expenditure was recorded in France, Italy, Australia and India. By contrast, tourists from Germany spent more than twice as much abroad (EUR 60.6 billion) as international tourists spent in Germany (EUR 27.9 billion). In fact, tourists from Germany spent more abroad than international tourists from any other G20 member (for which data are available).

The short time series presented in Table 3 shows that expenditure by international tourists from Brazil and China more than doubled between 2008 and 2011 and there were also large increases recorded for tourists from India and Russia. India, Australia and South Korea recorded relatively large increases in international tourism receipts between 2008 and 2011.

Information society

By 2011 several G20 members registered more mobile subscriptions than inhabitants

Telecommunication networks and services are the backbone of the information society. Individuals, enterprises and public organisations alike depend increasingly on convenient, reliable and high-speed telecommunication networks and services. During recent years a shift in the importance of various services can be noted, from wired networks to mobile networks and from voice services to data services. While the number of fixed telephone subscriptions relative to the size of the population increased between 2001 and 2011 in some of the G20 members, notably Indonesia, it was mobile subscriptions where the largest increases were generally recorded – see Figure 6. By 2011 several G20 members registered more mobile subscriptions than inhabitants (indicating that some users had more than one subscription), with the highest ratio of subscriptions to inhabitants in Saudi Arabia.

Table 4 shows that there was also widespread growth between 2001 and 2011 in the use of the internet, even among G20 members with already high usage in 2001. By 2011 Canada and South Korea topped the ranking of internet use, with more than four in every five inhabitants online, with Japan, Australia and the United States just below this level. The number of fixed broadband subscriptions relative to population size was more diverse, with South Korea and Canada exceeding 30 subscriptions per 100 inhabitants, whereas in South Africa, Indonesia and India this ratio was below 2 subscriptions per 100 inhabitants.

Table 5 provides a selection of key indicators concerning ICT usage in enterprises – it should be noted that the usage of ICT depends to some extent on enterprise size and the sector of operation, and so differences in

coverage can affect the comparability of results.

Data sources and availability

The statistical data were mainly extracted during June and July 2012.

The indicators are often compiled according to international – sometimes global – standards, for example, UN standards for national accounts and the IMF's standards for balance of payments statistics. Although most data are based on international concepts and definitions there may be certain discrepancies in the methods used to compile the data.

EU27 and euro area data

Almost all of the indicators presented for the EU27 and EA-17 aggregates have been drawn from Eurobase, Eurostat's online database. Eurobase is updated regularly, so there may be differences between data appearing in this publication and data that is subsequently downloaded. In exceptional cases some indicators for the EU have been extracted from international sources, for example, when values are expressed in purchasing power parities. Otherwise, European Commission sources have been used.

G20 countries from the rest of the world

For the 15 G20 countries that are not members of the EU, the data presented have generally been extracted from a range of international sources listed in the [Introduction](#). In a few cases the data available from these international sources have been supplemented by data for individual countries from national statistics authorities. For some of the indicators a range of international statistical sources are available, each with their own policies and practices concerning data management (for example, concerning data validation, correction of errors, estimation of missing data, and frequency of updating). In general, attempts have been made to use only one source for each indicator in order to provide a comparable analysis between the countries.

Context

Industrial activities such as manufacturing are integrated with many service activities such as transport and communications, distribution and business services, which in turn depend on industry to produce the equipment and hardware they use. Creating a positive climate in which entrepreneurs and businesses can flourish is considered by many as the key to generating growth and jobs; this is all the more important in a globalised economy, where some businesses have considerable leeway to select where they wish to operate.

Tobacco processing statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). The present article covers manufacture of all tobacco products, corresponding to [NACE Rev 1.1 Division 16](#), which is part of the [food, beverages and tobacco](#) sector. Tobacco products consist of:

- cigarettes;
- cigarette tobacco;
- cigars;
- pipe tobacco;
- chewing tobacco;
- snuff.

Table 2: Manufacture of tobacco products (NACE Division 16). Main indicators, 2006 (1)

The number of [enterprises](#) across the [EU-27](#) with tobacco manufacturing (NACE Division 16) as their main activity was just 0.3 thousand in 2006, demonstrating that this activity is particularly dominated by a few, extremely large [multi-national enterprises](#). There were an estimated 64.0 thousand persons employed within the EU-27's tobacco manufacturing activities in 2006, which equated to just 1.4% of the food, beverages and tobacco manufacturing workforce. Nonetheless, these activities generated EUR 8.3 billion of [value added](#), which was a significantly higher share (4.2%) of sectoral value added. Tobacco manufacturing was highly concentrated within the EU-27 in geographical terms too, with almost two thirds of the EU-27's value added coming from Poland (26.1% in 2005), the United Kingdom (20.4% in 2006) and Germany (18.0% in 2006). The Netherlands is also a key tobacco manufacturing Member State, although data are not yet available for years later than 2004 (when it accounted for 15.5% of the EU-27 total).

In relative terms, the value added generated by the tobacco manufacturing sectors of Poland and Bulgaria made much more significant contributions to total value added within their respective [non-financial business economies](#) than the EU average. The relative contribution of these activities in Poland was about ten times as high as the EU-27 average in 2005, and in Bulgaria it was about five times as high.

There was a strong downward trend in the [production index](#) of tobacco products across the EU-27 during the ten years through until 2007 with an average decline of 3.4% per year. The EU-27's [output](#) of tobacco products in 2007 remained close to its most recent low point recorded in 2006. In the Netherlands output grew rapidly through until 2002, after which there was a sharp decline, although the production index for 2007 remained 4.6% higher than in 1997. In Poland, there were considerable fluctuations from one year to the next, although the overall evolution of output followed a downward trend (losing an average of 1.5% per year), despite a considerable upturn in production in 2007. In Germany and the United Kingdom the downward trend was much more pronounced and sustained. In the United Kingdom, the production index in 2007 stood at 50% of its level of a decade earlier (corresponding to an average decline of 6.7% per year). The rate of decline in tobacco products manufacturing output in Germany was even more pronounced after 2000 (falling on average by 8.4% per year between 2000 and 2007).

Expenditure and productivity

[Personnel costs](#) across the EU-27

's tobacco manufacturing sector accounted for 12.2% of total operating expenditure in 2006, slightly below the average for the food, beverages and tobacco manufacturing sector. However, average personnel costs for

tobacco manufacturing (EUR 47.3 thousand per employee in 2005) were much higher than for any of the other nine NACE groups within food, beverages and tobacco manufacturing.

Despite this high level of average personnel costs, the [wage-adjusted labour productivity ratio](#) of those working in the tobacco manufacturing sector averaged 339.5% among those countries for which data are available¹⁴⁵, slightly more than double the ratio for the food, beverages and tobacco manufacturing sector. This high level of wage-adjusted labour productivity was based on EUR 170.0 thousand of value added being generated by each person employed in the EU-27's tobacco manufacturing sector in 2005, which was a little more than four times the corresponding level of the food, beverages and tobacco manufacturing sector.

The wage adjusted labour productivity ratio of those working in Poland's tobacco products manufacturing sector was particularly high (2560% in 2005), which, at least in part, helps explain why this ratio was particularly high for food, beverages and tobacco manufacturing as a whole (361.7% in 2005).

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include [short-term statistics \(STS\)](#), the [Labour force survey \(LFS\)](#), the [COMEXT](#) database for external trade and the [Confederation of Food and Drink Industries \(CIAA\)](#).

Context

The food, beverages and tobacco manufacturing sector in the EU is comprised of a relatively small number of enterprises that have a considerable global market presence, which operate alongside a high number of relatively small enterprises that serve more local, regional and national markets.

As these enterprises not only produce goods for final consumption but also intermediate products for other manufacturing activities, they are affected by a broad scope of legislation. The main legislative areas affecting the EU's food, beverages and tobacco manufacturing sector, however, tend to involve international trade agreements, or food and feed legislation. As a majority of the EU's agricultural production is processed by the [food, beverages and tobacco manufacturing sector](#), developments in [Common Agricultural Policy](#) and associated Common Market Organisations can have important implications for costs and processes in the food chain. Regarding food legislation, the [European Parliament](#) and the [Council](#) proposed an update of the laws regarding the provision of information to consumers ([COM\(2008\) 40 final](#)) in 2008, in order to clarify and consolidate existing regulations. In part, this proposal was built on a 2007 White Paper covering a Strategy for Europe on Nutrition, Overweight and Obesity ([COM\(2007\) 279 final](#)), which stressed the need for consumers to have access to clear, consistent and evidence-based nutritional information.

In July 2008, the [European Commission](#) presented a report and a proposal for a Directive ([COM\(2008\) 459 final](#)) to amend current EU excise duty legislation on tobacco. The draft Directive foresees a gradual increase in minimum taxation levels on cigarettes and fine cut tobacco up to 2014. The proposal also aims to contribute to reducing tobacco consumption by 10% within the next 5 years. The European Commission also reported on the implementation of the EU tobacco advertising Directive ([COM\(2008\) 330 final](#)) and the application of the tobacco products Directive ([COM\(2007\) 754 final](#)) as part of its drive to curb avoidable, tobacco-related deaths in EU.

Notes

Transport and storage statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article introduces a [set of statistical articles](#) which analyse the structure, development and characteristics of the economic activities in the transport and storage sector in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), this sector covers NACE Divisions 60 to 63, and its activities are treated in more depth in six further articles:

	Enterprises		Turnover		Value added		Persons employed	
	(thousand)	(% of total)	(EUR million)	(% of total)	(EUR million)	(% of total)	(thousand)	(% of total)
Transport and storage	1 137,8	100,0	1 209 490	100,0	400 768	100,0	8 847,4	100,0
Transport via railways (2)	0,8	0,1	66 645	6,0	31 881	8,4	880,7	10,1
Road and other land transport (3)	900,0	79,1	370 000	30,6	150 000	37,5	4 616,0	52,9
Transport via pipelines (4)	-	-	11 000	1,0	-	-	-	-
Water transport (3)	18,9	1,7	100 000	8,3	22 000	5,5	213,5	2,4
Air transport (5)	3,5	0,3	110 000	9,9	30 000	7,5	400,0	4,5
Warehousing and transport	109,6	9,6	384 271	31,8	139 837	34,9	2 186,1	24,7
Activities of travel agencies	78,2	6,9	153 203	12,7	19 272	4,8	484,7	5,5

(1) Rounded estimates based on non-confidential data.
(2) Turnover, value added and number of persons employed, 2005.
(3) Number of persons employed, 2005.
(4) Turnover, 2005.
(5) Number of enterprises and turnover, 2005.

Table 8: Warehousing and transport support activities; activities of travel agencies (NACE Division 63). Main indicators, 2006 (1)

- land transport by rail - NACE Rev. 1.1 (NACE Group 60.1);
- land transport by road - NACE Rev. 1.1 (NACE Group 60.2);
- land transport by pipelines - NACE Rev. 1.1 (NACE Group 60.3);
- water transport - NACE Rev. 1.1 (NACE Division 61);
- air transport - NACE Rev. 1.1 (NACE Division 62);
- warehousing and transport support activities - NACE Rev. 1.1 (NACE Groups 63.1, 63.2 and 63.4);

- [travel agencies - NACE Rev. 1.1](#) (NACE Group 63.3).

Main statistical findings

Structural profile

There were in excess of 1.1 million [enterprises](#) in the transport services sector (NACE Divisions 60 to 63) in the EU-27 which [employed](#) 8.8 million persons in 2006 in the EU-27, which represented 6.8% of those working in the [non-financial business economy](#) (NACE Sections C to I and K). This sector generated EUR 400.3 billion of [value added](#) in 2006 from [turnover](#) valued at EUR 1209.5 billion: equivalent to 7.1% of value added in the non-financial business economy and 5.4% of its turnover.

By far the two largest subsectors were road and other land transport (NACE Group 60.2, see [Road and other land transport statistics - NACE Rev. 1.1](#)) and warehousing and transport support activities (NACE Groups 63.1, 63.2 and 63.4, see [Warehousing and transport logistics statistics - NACE Rev. 1.1](#)) which each contributed more than one third of transport services value added. The next largest subsectors were rail transport (NACE Group 60.1, see [Rail transport statistics - NACE Rev. 1.1](#)) and air transport (NACE Division 62, see [Air transport sector statistics - NACE Rev. 1.1](#)) which each generated around EUR 30 billion of value added (in 2005 and 2006 respectively). Water transport (NACE Division 61, see [Water transport statistics - NACE Rev. 1.1](#)) and the activities of travel agencies (NACE Group 63.3, see [Travel agencies statistics - NACE Rev. 1.1](#)) were around two thirds of this size, with value added around EUR 20 billion in 2006. In employment terms the dominance of the single largest subsector, road and other land transport, was even greater, occupying more than one half of the EU-27's transport services workforce. Transport via railways and the activities of travel agencies were the only other subsectors whose contribution to transport services was greater in employment than in value added terms.

The United Kingdom had the largest transport services sector in value added terms while Germany had the largest workforce in this sector. In value added terms the [Baltic Member States](#) were the most specialised¹⁴⁶ in transport services, as they, as well as Luxembourg, generated 10% or more of their non-financial business economy value added in this sector. The transport services sector recorded its smallest shares of non-financial business economy value added in Germany, Slovakia and Ireland. In the case of Latvia, in value added terms transport services was the second largest of all the [structural business statistics](#) sectors, smaller only than wholesale trade.

An analysis of the regional specialisation based on the non-financial business economy employment share of this sector shows that there are a number of regions that have a very different level of specialisation from the average recorded for the country to which they belong. While the island region of Åland (Finland) is by far the most specialised region (at the level of detail shown in the map) in transport services, the next two most specialised regions, Bratislavský kraj (Slovakia) and Bremen (Germany), are both in Member States which had a particularly low value added specialisation in transport services.

The development of the EU-27 turnover indices between 2000 and 2007 for transport services NACE divisions shows that the strongest growth was for water transport, with average growth of 7.2% per year over this period. Land transport and transport via pipelines recorded average growth that was only slightly slower (6.9% per year). Average growth in warehousing, transport support activities and activities of travel agencies (6.2% per year) and air transport (5.4% per year) was somewhat lower still, but nevertheless above the non-financial services (NACE Sections G to I and Divisions 72 and 74) average in both cases.

During the period from 2000 to 2007, there was a negative rate of change in the turnover index for water transport in 2002 (-3.9%) and for air transport in 2001 (-1.1%), the latter reflecting a general economic slowdown as well as a number of exceptional circumstances. Whilst air transport recorded the lowest average growth over the seven-year period studied, in the most recent years for which data are available (2005 to 2007) it recorded double-digit growth each year, with the highest sales growth among the four transport services NACE divisions in two of these three years.

EU-27 employment indices are available for transport services NACE divisions from 1998, and these show a contrasting development in the various activities. The strongest growth was for warehousing, transport support activities and activities of travel agencies, for which growth averaged 3.0% per year over this nine-year period, with growth recorded each and every year. This was the only one of the four transport services NACE

¹⁴⁶Bulgaria, Cyprus, Poland and Romania, 2005; Malta and the Netherlands, not available.

divisions that recorded average employment growth above the non-financial services average (2.3%). Air transport recorded an annual average growth rate of 0.5%, but this was composed of strong growth in 1999 and 2000, followed by a more gentle decline most years since then, with the 1.0% increase of 2006 the only significant recent employment gain in this subsector. Land transport and transport via pipelines also recorded overall growth during this period, a more modest 0.2% per year average. This resulted from a relatively strong fall in employment in 1999 and 2000, followed by a period of relatively stable employment, with more rapid expansion in the last two years for which data are available. Water transport was the only transport services NACE division to record an overall fall in employment between 1998 and 2007, averaging 2.2% per year. This was, however, due to a very strong fall in employment in 1999, 2000 and to a lesser extent 2001 and 2002. Since then the water transport employment index only fell once (-0.6% in 2006), and averaged growth of 1.1% per year over the period 2002 to 2007.

Size class data show that **large enterprises** (with 250 or more persons employed) played an important role in transport services, with close to half (48.5%) of the sector's value added and more than two fifths (40.7%) of its employment within the EU-27 in 2006: in both cases this was well above the non-financial business economy average. All three of the other size classes contributed less in employment and value added terms to the transport services total than they did to the non-financial business economy total. Behind these averages for the transport services sector lies a distinction, essentially between air and rail transport which are dominated by large enterprises on one hand, and the remaining transport services which are characterised by an employment contribution from large enterprises closer to the average for the non-financial business economy. The information that is available for a few Member States illustrates that transport via railways is dominated by large enterprises to a greater extent than in nearly any other activity: in Germany large enterprises contributed 93.2% of employment in rail transport in 2006, while the equivalent share in the United Kingdom was 98.6%. Equally, large enterprises accounted for a large share of air transport employment, exceeding 60% in all of the Member States with data available for 2006. The importance of large enterprises in the EU-27's air transport sector was such that they accounted for 93.2% of this activity's employment in 2006: this was the second highest employment share of large enterprises among all of the non-financial business economy NACE divisions¹⁴⁷ in 2005 or 2006, only smaller than for the mining of coal and lignite and the extraction of peat (NACE Division 10).

Transport of goods and passengers

Over several decades, road and sea transport of goods increased strongly in the EU, while the volume of goods transported by inland waterways was relatively stable and rail freight transport declined. For the EU-27 around ten years of data is now available for most modes of transport, and this provides an insight into the changes in more recent periods for both goods and passengers. Since 1996 the use of road freight transport increased steadily and strongly, and by 2006 its share (in terms of **tonne-kilometres**) of total freight (excluding air transport and extra-EU-27 sea transport) was approaching 50%. Rail, pipeline and inland water freight transport, as well as intra-EU sea transport all increased in terms of tonne-kilometres transported, but their share of total freight transport decreased (only slightly for sea freight transport).

EU-27 sea passenger transport displayed a fall in the number of passenger-kilometres transported every year from 1995 onwards, with the exception of 2003. The fall in 2005 was particularly strong, down 2.4%. In contrast, rail passenger transport recorded growth most years from 1997 onwards, with falls recorded only in 2002 and 2003. Growth was particularly strong in the two most recent years, 2.8% recorded in 2005, and 2.7% in 2006. Other collective land passenger transport such as buses, metros, trams and coaches also recorded relatively stable increases in their respective volumes of passenger transport, generally stronger for trams and metros than for buses and coaches.

In the EU-27 the fastest increase in passenger transport over the period considered was recorded for air transport, as its share of total passenger transport (in terms of **passenger-kilometres**) rose from 6.6% in 1996 to 8.6% by 2006. The relatively stable modal share of **passenger cars** reflects a growth rate in the use of passenger cars that was slightly higher than the rates recorded by all other forms of passenger transport (except for air transport).

¹⁴⁷NACE Divisions 11 and 12, not available.

Employment characteristics

On the basis of [Labour force survey](#) data, transport services clearly stand out from most other service activities in terms of their gender profile. Only 20.9% of those persons employed in this sector in 2007 in the EU-27 were women, around three fifths of the average for the non-financial business economy where women accounted for 35.1% of those employed. In land transport and transport via pipelines (NACE Division 60) the share of women in the workforce was just 13.5%, among the lowest shares across the non-financial business economy NACE divisions, higher only than in construction and two mining and quarrying (NACE Section C) divisions. The share of women in the workforce was also particularly low in water transport, 19.9%, and just below the non-financial business economy average in warehousing, transport support activities and the activities of travel agencies (32.4%). The only one of the four transport services NACE divisions where the share of women in the workforce was above the non-financial business economy was air transport where 40.7% of the workforce was female.

Part-time work was also less common in transport services than in other activities, since 90.9% of those employed in transport services in the EU-27 in 2007 worked on a full-time basis, compared with a non-financial business economy average of 85.7%. The high incidence of full-time employment was observed in three of the transport services NACE divisions, particularly so in water transport (94.2%) and land transport and transport via pipelines (92.7%). The lowest rate of full-time employment was recorded for air transport (84.3%), just 1.4 percentage points below the non-financial business economy average.

The age profile of the transport services workforce was also markedly different from the non-financial business economy average. The proportion of the EU-27 transport services workforce aged 15 to 29 was 17.7% in 2007, some 6.7 percentage points below the average for the non-financial business economy. This was reflected in an above average share of older workers (aged 50 or more) representing more than one quarter (25.7%) of the workforce, compared with just over one fifth (21.9%) for the non-financial business economy as a whole. All of the transport services NACE divisions recorded a relatively low proportion of younger workers, but this was most notable for land transport and transport via pipelines where the proportion was as low as 14.1%, one of the lowest among the non-financial business economy NACE divisions, higher only than in some mining and quarrying (NACE Section C) divisions. Air transport was the only transport services NACE division where the proportion of older workers (20.0%) was below the non-financial business economy average, while the highest proportion of older workers was recorded for land transport and transport via pipelines and for water transport services (both 27.8%).

Expenditure, productivity and profitability

Transport services reported high gross [tangible investment](#), EUR 114.1 billion in 2006 in the EU-27, equivalent to 11.0% of the total within the non-financial business economy, a share far greater than this sector's employment or value added shares. As such, the [investment rate](#) (investment compared to value added as a percentage) in transport services was 28.5%, just over 10 percentage points higher than the non-financial business economy average (18.4%). Water transport recorded a particularly high investment rate (45.5%) in 2006, as did warehousing and transport support activities (34.7%). In 2005, the three subsectors that make up land transport and transport via pipelines (NACE Divisions 60) recorded a combined investment rate of 27.0%, and air transport recorded a rate of 24.8%, in both cases below the transport services average but above the non-financial business economy average. By this measure one of the transport services subsectors stood out from the others, and this was the activities of travel agencies where gross tangible investment was equivalent to just 7.8% of value added.

An analysis of [operating expenditure](#) indicates that transport services use a relatively large amount of labour, with [personnel costs](#) accounting for around 22.5% of operating expenditure in the EU-27 in 2006, approximately 1.4 times the average share in the non-financial business economy. This share was particularly high for transport via railways (38.6%, 2005), and road and other land transport (30.3%), while it was particularly low for the activities of travel agencies (8.1%), an activity that often involves relatively high purchases of goods and services that are resold to customers.

The high levels of full-time employment may, to some extent, explain why average personnel costs faced by transport services enterprises were generally high: in transport services they averaged EUR 31.3 thousand per employee in 2006 in the EU-27 compared with EUR 28.8 thousand for the non-financial business economy as a whole. The relatively high level of average personnel costs impacted on the [wage-adjusted labour productivity](#)

[ratio](#) , which represents the extent to which value added per person employed covers average personnel costs per employee. In the EU-27's transport services sector this ratio was 144.5% in 2006, below the non-financial business economy average of 151.1%. There were considerable differences in the value of this ratio between the transport services subsectors, with a particularly high ratio for water transport (280.0%, 2005). No recent data is available for transport via pipelines, but in all six of the Member States with 2005 or 2006 data available for this subsector the wage-adjusted labour productivity ratio was in excess of 500%.

In contrast, the [gross operating rate](#) ([gross operating surplus](#) relative to turnover) was higher for transport services (12.9%) in 2006 than the non-financial business economy average (10.8%). An exceptionally high gross operating rate (40.0%, 2005) was recorded for transport via pipelines, the highest rate among all non-financial business economy NACE groups with data available.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include [short-term statistics \(STS\)](#) , the [Labour force survey \(LFS\)](#) and [Eurostat](#) , ITF, UIC, national statistics, estimates, in EU energy and transport in figures statistical pocketbook 2007/2008, European Commission, Directorate-General for Energy and Transport.

Context

The transport and storage sector focuses on transport services provided to clients for hire and reward. When analysing transport traffic volumes (for example, tonnes of freight) as presented in this article, it is important to bear in mind that these include own account transport as well as transport services for hire and reward. This is particularly important in road transport where, for example, a manufacturer might collect materials or deliver own output, rather than contracting a transport service enterprise to do this. Equally, the use of own vehicles (typically passenger cars) accounts for a very large part of passenger transport. Such own account transport does not contribute towards the statistics on the transport services sector.

EU transport policy is based upon the [2001 White paper 'European transport policy for 2010: time to decide'](#) and the 2006 mid-term review in the European Commission's communication ([COM\(2006\) 314](#)) 'Keep Europe moving – sustainable mobility for our continent'. In 2007 the European Commission adopted a communication ([COM\(2007\) 606](#)) on 'Keeping freight moving', to make rail freight more competitive, facilitate modernisation of ports, and review progress in the development of sea shipping.

Environmental issues remain of great importance to this sector, as transport is a major source of emissions and noise. In 2008 the European Commission put forward a package of measures related to road and rail transport referred to as 'Greening Transport'. This included a communication ([COM\(2008\) 433](#)) summarising the packages and initiatives planned for 2009, a strategy to internalise the cost of transport externalities, a proposal for a Directive on road tolls for lorries, and a communication on rail noise. The overall thrust of the package is to try to move towards more sustainable transport.

Notes

Transport equipment production statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article introduces a [set of statistical articles](#) which analyse the structure, development and characteristics of the economic activities in the transport equipment sector in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), this sector covers two NACE divisions, which are:

- the manufacture of motor vehicles (corresponding to NACE Division 34);
- the manufacture of other types of transport equipment: shipbuilding, railway rolling stock, aerospace equipment, motorcycles and bicycles, and other transport equipment (NACE Division 35).

The activities of the transport equipment sector are treated in more depth in five further articles, which cover the production of:

- [cars](#) (NACE Division 34);
- [ships and boats](#) (NACE Group 35.1);
- [railway equipment](#) (NACE Group 35.2);
- [aerospace equipment](#) (NACE Group 35.3);
- [motorcycles, bicycles and miscellaneous transport equipment](#) (NACE Groups 35.4 and 35.5).

	Enterprises		Turnover		Value added		Persons employed

Table 7: Manufacture of other transport equipment (NACE Division 35). Main indicators, 2006 (1)

The EU-27's transport equipment manufacturing sector (NACE Subsection DM) consisted of 45.7 thousand enterprises which employed 3.2 million persons in 2006. Paid employees dominated this workforce, accounting for 98.6% of all persons employed: this proportion was above the non-financial business economy average (86.5%) as well as the industrial average (94.2%) and in most of the subsectors the proportion reached 99.0% or higher.

In terms of output, the EU-27's transport equipment manufacturing sector was substantial, generating EUR 195.0 billion of value added in 2006, the fifth largest amount among the industrial structural business statistics sectors. The transport equipment manufacturing sector accounted for 3.5% of the value added created within the EU-27's non-financial business economy (NACE Sections C to I and K) and employed 2.4% of the non-

financial business economy workforce.

The transport equipment manufacturing sector is dominated by the manufacture of motor vehicles, trailers and semi-trailers (NACE Division 34), as this activity represented 73.9% of sectoral value added in 2006. Among the EU-27's other transport equipment manufacturing (NACE Division 35) activities, the manufacture of aerospace equipment (NACE Group 35.3; [Aerospace equipment production statistics]) was by far the largest activity in 2006, with a 15.4% share of value added for the whole of the transport equipment manufacturing sector. These two larger subsectors (motor vehicles and aerospace) both accounted for smaller shares of the sector's workforce than of the sector's value added, whereas the three smallest subsectors, namely the building and repairing of ships and boats (NACE Group 35.1), the manufacture of railway and tramway locomotives and rolling stock (NACE Group 35.2), and the manufacture of miscellaneous transport equipment (NACE Groups 35.4 and 35.5) had larger employment than value added shares.

Germany dominated the EU-27's transport equipment manufacturing sector: Germany's EUR 78.7 billion of value added in this sector was just over two fifths of the EU-27 total in 2006, and its workforce of close to 1 million persons was just over three tenths of the EU-27 total. It was not just in absolute size that Germany dominated this sector, as it was also the most specialised Member State, in that this sector contributed more to non-financial business economy value added (6.8%) and non-financial business economy employment (4.6%) in Germany than in any other Member State, and it was in this sector that Germany recorded its highest contribution to EU-27 value added of any of the industrial NACE subsections.

The manufacture of transport equipment was particularly concentrated within the larger Member States, as Germany, France (13.8% of EU-27 value added) and the United Kingdom (13.0%) had a cumulative share of EU-27 value added equal to 67.2% in 2006, compared with their 53.5% share of non-financial business economy value added. This high level of concentration meant that relatively few of the Member States were specialised in the manufacture of transport equipment in value added terms, with only the top five (as listed in Table 12.2) reporting that their respective transport equipment manufacturing sectors contributed more to national non-financial business economy value added than the EU-27 average in 2006. Several Member States were specialised in particular subsectors, notably Bulgaria, Greece, Lithuania and Finland in the building and repairing of ships and boats, and Italy in the manufacture of miscellaneous transport equipment (in particular motorcycles and bicycles).

The regional specialisation of transport equipment manufacturing in [employment](#) terms is shown in the map. The top two most specialised regions (at the level of detail shown in the map) were both in Germany, and German regions occupied seven of the top ten places. Among the Member States that joined the EU in 2004 or 2007 several regions in the Czech Republic, Hungary, Poland, Romania and Slovakia were relatively specialised in this sector.

Changes in the EU-27 [index of production](#) for the manufacture of transport equipment generally took place at a more rapid pace than the industrial average during the ten years to 2007. On average, output rose by 3.9% per year compared with 2.1% for the industrial economy as a whole. Year on year growth rates recorded for transport equipment manufacturing exceeded those for the industrial economy in each year from 1997 to 2007, except in 2002 when production fell by 0.4% for the industrial economy as a whole and by 0.5% for transport equipment manufacturing. Transport equipment manufacturing output growth exceeded 4% in three of the last four years in the EU-27: several Member States in central and eastern Europe recorded high annual growth in the five years to 2007, ranging from a high of 22.7% in Lithuania to growth in excess of 9% per year over this period in Poland, Slovakia, Bulgaria, Romania the Czech Republic, Hungary and Estonia.

The growth in output for the EU-27 as a whole was largely driven by the manufacture of motor vehicles, trailers and semi-trailers, where the index of production rose on average by 4.4% per year in the ten years to 2007, while for other transport equipment manufacturing growth averaged 2.1% per year during the same period. A more detailed analysis of the development of the production index focusing on the largest activities shows that over the ten years to 2007 aircraft and spacecraft manufacturing recorded fairly sustained output growth in the EU-27, with one notable fall in 2002 and a smaller one in 2006. The building and repairing of ships and boats showed a decline in output until 2004, after which three years of output growth were recorded, particularly strong in 2006 and 2007. Railway equipment manufacturing output fell sharply in 2000, since when growth has been recorded more often than not.

Transport equipment manufacturing employment within the EU-27 peaked most recently in 2001, after which the employment index declined gently for five consecutive years. In 2007 this downward trend was reversed, with employment growth around 1.0%.

Transport equipment output prices in the EU-27 grew steadily over the ten years to 2007, with lower rates of change than for industry as a whole, most notably since 2002. During the five years from 2002 to 2007 output prices for transport equipment manufacturing increased by 1.2% per year on average, compared to an industrial average of 3.7%.

The manufacture of transport equipment was concentrated within relatively large enterprises, as **SMEs** (employing less than 250 persons) generated just 13.8% of the EU-27's value added in 2006, compared with a non-financial business economy average of 57.9%. This was by far the lowest value added contribution of SMEs recorded for any of the structural business statistics sectors. The dominance of **large enterprises** (with 250 or more persons employed) was particularly prevalent within the manufacture of motor vehicles, trailers and semi-trailers (NACE Division 34) where they accounted for 88.0% of value added and 82.1% of employment. Furthermore, the importance of large enterprises was particularly marked in Germany where they accounted for 93.8% of value added in transport equipment manufacturing in 2006, and this share was also¹⁴⁸ over 90% in Hungary, the Czech Republic and France.

Employment characteristics

The most notable characteristics of the transport equipment manufacturing workforce are the high proportions of men in the workforce and the very high propensity to employ on a full-time basis. Men accounted for 81.5% of the EU-27's transport equipment manufacturing workforce in 2007, compared with a non-financial business economy average of 64.9%. The proportion of the workforce that was male was above the non-financial business economy average for both the manufacture of motor vehicles, trailers and semi-trailers (79.4%) and in particular the manufacture of other transport equipment (86.4%). As many as 96.3% of the EU-27's transport equipment manufacturing workforce worked on a full-time basis in 2007.

In terms of the age profile of the EU-27's transport equipment manufacturing workforce there was little difference compared with the non-financial business economy average when analysed according to the three age classes presented. Comparing the age structure of the two NACE divisions in this sector, the most notable difference was the proportion of the workforce that was aged 50 or over, which was 20.4% in the manufacture of motor vehicles, trailers and semi-trailers, compared with 25.9% for the manufacture of other transport equipment. Among the Member States the age profile of the transport equipment manufacturing workforces in Poland and Slovakia stood out, with more than one third of the workers aged less than 30.

Expenditure, productivity and profitability

In 2006, the transport equipment manufacturing sector recorded a level of gross **tangible investment** of EUR 31.6 billion, some 3.0% of the total within the EU-27's non-financial business economy. Investment in this sector was equivalent to 16.2% of value added, 2.2 percentage points below the average **investment rate** for the EU-27's non-financial business economy, and fractionally below the industrial average (16.6%). The investment rate was slightly higher for the manufacture of motor vehicles, trailers and semi-trailers subsector, and lower in all of the other subsectors. Slovakia and Slovenia recorded the highest investment rates in this sector in 2006, 93.5% and 70.3% respectively. In several Member States tangible investment in transport equipment manufacturing reached 5% of all tangible investment in the non-financial business economy, most notably in Slovakia, the Czech Republic, Hungary and Germany.

An analysis of **operating expenditure** shows that the transport equipment manufacturing sector in the EU-27 did not differ greatly from the non-financial business economy average: 15.9% of operating expenditure was devoted to personnel costs in this sector, compared with a non-financial business economy average of 16.1%. However, this share was lower in the largest subsector, the manufacture of motor vehicles, trailers and semi-trailers, where the share was 14.2%, while it was notably higher for the manufacture of aerospace equipment (26.3%) and the manufacture of railway and tramway locomotives and rolling stock (24.2%).

In terms of average **personnel costs**, **productivity** and **profitability** the EU-27's transport equipment sector diverged significantly from the industrial and non-financial business economy averages. Average personnel costs were EUR 46.4 thousand per employee, some EUR 17.6 thousand per employee higher than the non-financial

¹⁴⁸The Netherlands and Poland, 2005; Estonia and Malta, incomplete or not available.

business economy average. Most of the subsectors, however, recorded much lower average personnel costs, just over EUR 30.0 thousand per employee, and therefore below the industrial average; the high transport equipment manufacturing average resulted from higher average personnel costs in the two largest subsectors, notably the manufacture of aerospace equipment. A similar pattern could be observed for apparent [labour productivity](#), with the smaller subsectors recording averages below the industrial average, and the two larger subsectors, led by the manufacture of aerospace equipment, recording higher averages. As a result, the transport equipment manufacturing sector recorded apparent labour productivity above the industrial average, reaching EUR 61.9 thousand per person employed.

The relatively high apparent labour productivity combined with the particularly high average personnel costs, resulted in a [wage-adjusted labour productivity ratio](#) of 133.3% for the EU-27's transport equipment manufacturing sector in 2006, well below the 151.1% average ratio recorded for the non-financial business economy. None of the transport equipment subsectors recorded high wage-adjusted labour productivity ratios, the highest being 137.7% for the manufacture of miscellaneous transport equipment, while the lowest was 124.1% for the building and repairing of ships and boats. Among the Member States, the only Member State to record a wage-adjusted labour productivity ratio below parity (100%) was Ireland, which in fact recorded a negative ratio due to negative value added in this sector. Hungary and Poland (2005) recorded by far the highest wage-adjusted labour productivity ratios in this sector, and in both cases these were well above the average ratios for their non-financial business economies, as was also the case in the Czech Republic, Slovenia and Austria.

The gross [operating rate](#) for the EU-27's transport equipment manufacturing sector was also low (5.4%), half the non-financial business economy average (10.8%), as high average personnel costs kept the gross [operating surplus](#) low. This was the lowest gross operating rate of any industrial NACE subsection. In none of the EU-27's transport equipment manufacturing subsectors did the gross operating rate exceed the non-financial business economy average in 2006, the highest being 8.4% for the manufacture of railway and tramway locomotives and rolling stock.

External trade

Just over two thirds (68.5%) of [exports](#) of transport equipment (CPA Subsection DM) by the EU-27 Member States were destined for other Member States, in other words [intra-EU](#) trade. This share was slightly higher than the average for all industrial products (CPA Sections C to E). Germany was by far the largest EU exporter of transport equipment in 2007, with exports to the rest of the world valued at EUR 208.0 billion, some 34.2% of the total for all Member States. France (13.5%) was the only other Member State to report a double-digit share of exports among the EU-27 Member States. The largest shares of industrial exports accounted for by transport equipment were 27.4% in Spain and 26.0% in Slovakia.

The EU-27 ran a significant [trade surplus](#) with non-member countries for transport equipment which was valued at EUR 81.2 billion in 2007, the second highest surplus among the industrial structural business statistics sectors. Exports from the EU-27 were valued at EUR 191.4 billion, and [imports](#) at EUR 110.2 billion, 16.4% and 8.3% respectively of industrial trade. Over two thirds (67.8%) of exports were accounted for by motor vehicles, trailers and semi-trailers (CPA Division 34), while in contrast, only just over half (54.2%) of the imports were accounted for by the same products. These differences in the respective shares of transport equipment exports and imports were reflected in the EU-27's trade surplus for motor vehicles, trailers and semi-trailers (EUR 70.1 billion). Trade in aircraft and spacecraft (CPA Group 35.3) dominated other transport equipment, with exports of EUR 41.5 billion in 2007 generating a trade surplus of EUR 11.2 billion. Trade surpluses just over EUR 2 billion were recorded for ships and boats as well as for railway and tramway locomotives and rolling-stock (CPA Groups 35.1 and 35.2), while a [deficit](#) of EUR 4.5 billion was recorded for motorcycles and bicycles (CPA Group 35.4). In 2007 the United States retained its position as the most important market for EU-27 exports of transport equipment, although its share declined.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include [short-term statistics \(STS\)](#) , the [Labour force survey \(LFS\)](#) and the [COMEXT](#) database for external trade.

Context

The transport equipment manufacturing sector is central to economic development, as it provides the means for transporting both individuals and goods. Demand for transport equipment has risen as the volume of goods transported and the distance travelled by passengers have expanded greatly – see the article on [transport and storage statistics](#) for information on transport flows.

The issue of sustainable development is likely to play an important role in future product developments, as transport equipment manufacturers try to meet demands for more environmentally friendly transport solutions, for example, engines with lower fuel consumption or emissions.

Most transport equipment manufacturing activities are structured on the basis of complex pyramidal relationships between major manufacturers and several tiers of component suppliers, ranging from systems suppliers down to very small, specialised manufacturers that may provide a single component for a vehicle. It is common to find clusters of enterprises concentrated in regions around the leading producers.

Notes

Transportation and storage statistics - NACE Rev. 2

Data from April 2012, most recent data: Further Eurostat information, Main tables and Database

This article presents an overview of statistics for the [European Union's \(EU's\)](#) transportation and storage services sector, as covered by [NACE Rev. 2](#) Section H. Transportation services concern passenger and freight transport, whether scheduled or not, regardless of the transport mode, and also include postal and courier services. Furthermore, the transportation and storage services sector covers warehousing and storage, alongside transport support activities such as terminal and parking facilities (bus and train stations, harbours, airfields, car parks), infrastructure operations (such as rail networks, waterway locks, roads, bridges, tunnels, air traffic control), support services (towing, shunting, berthing, pilotage), cargo handling and freight forwarding. The sector is mainly structured according to the different modes of transport, and contains five different NACE divisions, as follows:

- land transport by rail, road and pipeline (Division 49);
- sea and coastal water transport and inland water transport of freight and passengers (Division 50);
- passenger air transport, as well as freight air transport and space transport (Division 51);
- warehousing and support activities for transportation (Division 52);
- postal and courier activities (Division 53).

The transportation and storage services sector does not include the major repair or alteration of transport equipment which is part of repair activities within the [manufacturing](#) sector (Section C), nor the construction, maintenance and repair of transport networks (such as roads and railways) or terminals (such as harbours and airfields) which is part of the [construction](#) sector (Section F). Travel agencies and tour operators are also excluded as these are covered within [administrative and support service activities](#) (Section M). Training in the operation of transport equipment is considered as an education activity, while the operation of marinas is considered part of sports activities and amusement and recreation activities (note that both of these activities lie outside the delineation of the non-financial business economy and are traditionally not covered by structural business statistics).

The transportation and storage services sector focuses on transport services provided to clients for hire and reward. When analysing transport traffic volumes (for example, tonnes of freight) it is important to bear in mind that these include own account transport as well as transport services for hire and reward. This is particularly important in road transport where, for example, a manufacturer might collect materials or deliver own output, rather than contracting a transport service enterprise to do this and equally, the use of own vehicles (typically passenger cars) accounts for a very large part of passenger transport. Such own account transport does not contribute towards the statistics on the transportation and storage services sector.

	Value
Main indicators	
Number of enterprises (1 000)	1 110

Table 4b: Key indicators, transportation and storage (NACE Section H), 2009 - Source: Eurostat (sbs_na_1a_se_r2)

Main statistical findings

Structural profile

In 2009 there were around 1.1 million enterprises in the transportation and storage sector in the EU-27, equivalent to 5.3% of the non-financial business economy (Sections B to J and L to N and Division 95) enterprise population. These enterprises employed 10.6 million persons and added EUR 436600 million of value, which represented 7.8% of those working in the non-financial business economy and 7.9% of the wealth generated. The relatively low share of transportation and storage services in the enterprise population indicates that the average size of transportation and storage enterprises (in value added or employment terms) was above the non-financial business economy average; indeed, this sector includes some activities which are dominated by very large enterprises, for example, postal services, air and rail transport.

Several indicators based on labour input show this sector to be quite typical of the non-financial business economy as a whole. The [apparent labour productivity](#) of the EU-27's transportation and storage services sector in 2009 was EUR 41 thousand per person employed, which was almost identical to the non-financial business economy average (EUR 41.6 thousand per person employed). [Average personnel costs](#) were EUR 31.2 thousand per employee, which was marginally higher than the non-financial business economy average (EUR 30.0 thousand per employee).

In contrast the [gross operating rate](#) (the relation between the [gross operating surplus](#) and [turnover](#)) was 12.2% in the EU-27's transportation and storage services sector in 2009, which was above the non-financial business economy average (9.7%), even though it was the lowest rate among the NACE sections within non-financial services (Sections H to J and L to N and Division 95).

Sectoral analysis

In value added terms, the largest subsector (at the division level) in the EU-27's transportation and storage services sector was that of land transport and transport via pipelines (Division 49), which accounted for more than two fifths (43.7%) of sectoral value added in 2009, followed by warehousing and transport support activities (Division 52) which had a share of just under one third (32.4%). Postal and courier activities (Division 53) was the only other subsector to record a double-digit share of sectoral value added (13.7%), while water and air transport (Divisions 50 and 51) each accounted for just over 5% of the total.

The land transport and transport via pipelines share of employment was notably larger, as this subsector employed more than half (54.8%) of the EU-27's transportation and storage services sector's workforce in 2009, while the postal and courier activities subsector also accounted for a larger share of the sectoral employment (17.0%) than it did of sectoral value added. The three other subsectors accounted for smaller shares of the transportation and storage services sector's workforce, most notably the water transport subsector (2.1%).

Consequently, the subsectors recorded quite different levels of apparent labour productivity in 2009. The water transport subsector recorded the highest apparent labour productivity among the five divisions, with an average of EUR 99 thousand per person employed across the EU-27 which was some 60-70% higher than the corresponding levels recorded for air transport and for warehousing and support activities for transportation (where the second and third highest levels of apparent labour productivity were posted). The two remaining subsectors, namely, land transport and transport via pipelines and postal and courier activities recorded identical and much lower levels of apparent labour productivity (EUR 33 thousand per person employed), well below the non-financial business economy average (EUR 41.6 thousand per person employed).

Average personnel costs rose as high as EUR 64.1 thousand per employee in 2009 for the EU-27's air transport subsector, more than double the non-financial business economy average (EUR 30.0 thousand per employee). As for apparent labour productivity, the lowest average personnel costs were recorded for land transport and transport via pipelines (EUR 26.9 thousand per employee) and for postal and courier activities (EUR 28.5 thousand per employee), and as such both of the subsectors had average personnel costs that were below the non-financial business economy average.

As a consequence of its very high apparent labour productivity, the water transport subsector recorded the highest [wage-adjusted labour productivity ratio](#) among the five transportation and storage services subsectors, with apparent labour productivity equivalent to 201.1% of the average personnel costs. Warehousing and support activities was the only other transportation and storage services subsector to record a wage-adjusted labour productivity ratio (165.9%) above the non-financial business economy average (138.8%). The extremely high average personnel costs recorded within the air transport subsector exceeded apparent labour productivity and resulted in a wage-adjusted labour productivity ratio that was below parity (94.5%), contributing to a negative gross operating rate (-0.9%). Indeed, the air transport subsector was the only one of the five NACE divisions within the EU-27's transportation and storage services sector to record a gross operating rate below the non-financial business economy average (9.7%); the highest rate was posted for warehousing and support activities for transportation (15.6%).

Country analysis

Germany had the highest level of value added among the Member States in three of the five transportation and storage services subsectors that are shown in Table 3, with its share of EU-27 added value rising to more than one third (36.5%) for water transport, while its share of EU-27 value added for warehousing and transport support activities and postal and courier activities was between one quarter and one fifth (22.0% and 23.3% respectively). There was also a relatively high degree of concentration within the air transport subsector, where the United Kingdom had the highest share (24.4%) of EU-27 value added, while there was a wider distribution of value added within the land transport and transport via pipelines subsector – France recording the highest share (18.4%).

The Member State most specialised in the transportation and storage sector in employment terms was Denmark, as 15.5% of the Danish non-financial business economy workforce was employed in this sector; note that these Danish figures refer to 2008 and that the financial and economic crisis may have had a considerable impact in 2009). Nevertheless, the Danish employment share was far ahead of the next most specialised Member State, as Latvia recorded a 12.6% share in 2009. The high Danish specialisation was mainly due to a particularly high specialisation in land transport which alone accounted for 11.9% of the non-financial business economy workforce.

All of the [Baltic Member States](#) reported that a relatively large share of non-financial business economy value added was generated in the transportation and storage services sector, ranging from a high of 17.3% in Latvia to 12.5% in Estonia in 2009. Lithuania reported the highest degree of specialisation for the land transport and transport via pipelines subsector, while Latvia had the highest specialisation in the warehousing and transport support activities subsector. Denmark was the most specialised Member State in the water transport subsector (2008), followed by the Netherlands. Ireland and the United Kingdom were the most specialised Member States in the air transport subsector, while Italy was the most specialised country for postal and courier activities.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

EU transport policies aim to foster clean, safe and efficient travel throughout Europe, underpinning the internal market for goods and the right of citizens to travel freely throughout the EU. This policy is based upon a 2011 White paper – [Roadmap to a Single European Transport Area – Towards a competitive and resource efficient transport system](#), which included 40 specific initiatives to build a competitive transport system and aims to increase mobility, remove major barriers in key areas, and fuel growth and employment. At the same time, the proposals endeavour to dramatically reduce Europe's dependence on imported oil and cut carbon emissions in transport by 60% by 2050. Key goals to be achieved by 2050 include: no more conventionally-fuelled cars in cities; 40% use of sustainable low carbon fuels in aviation; at least a 40% cut in shipping emissions; a 50% shift of medium distance intercity passenger and freight journeys from road to rail and/or waterborne transport.

In most Member States, universal service providers still operate as a monopoly and have exclusive rights within the postal market, balanced by the fact that they have a universal service obligation. Indeed, postal services are of vital importance for commercial users and households alike and are considered as a service of general economic interest. Private operators dominate the express services market, providing letter and parcel services, specifically to the business-to-business, direct mail and business-to-private segments of the market. Since the middle of the 1990's there have been gradual developments towards market liberalisation for postal and courier services, with parcels and express services markets now fully open to competing operators. The latest amendment (2008/6) of the European Parliament and of the Council to the 1997 [Directive on Community postal services](#) was adopted in February 2008 and set out a timetable to abolish restrictions that remain for mail deliveries under 50 grams (known as the 'reserved area' for national operators) and open up Europe's postal services market to full competition. The deadline for full market opening was the end of 2010 for 16 of the

Member States (which represent 95% of the internal postal market), with a transitional period until the end of 2012 for the remainder. In 2010, there was a European Commission Decision taken [establishing the European Regulators Group for Postal Services](#) , its role is to:

- advise and assist the Commission in consolidating the internal market for postal services;
- advise and assist the Commission on any matter related to postal services within its competence;
- advise and assist the Commission as to the development of the internal market for postal services and as to the consistent application in all Member States of the regulatory framework for postal services;
- consult, in agreement with the Commission, extensively and at an early stage of its expert work with market participants, consumers and end-users in an open and transparent manner.

Travel agencies statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers travel agencies statistics, corresponding to NACE Group 63.3, which is part of the [transport and storage](#) sector. Travel agencies are enterprises that are engaged in arranging transport, accommodation and catering on behalf of travellers.

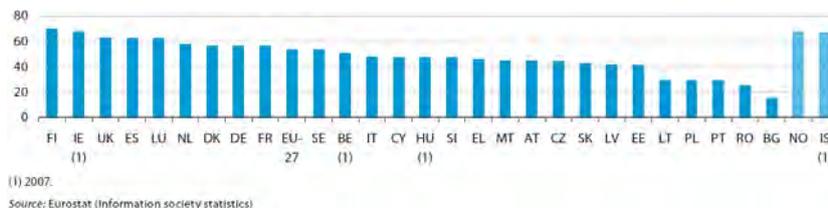

Figure 1: Activities of travel agencies and tour operators; tourist assistance activities n.e.c. (NACE Group 63.3). Proportion of individuals (aged 16 to 74) who use the Internet, who used the Internet for travel and accommodation services in the three months prior to the survey, 2008 (%)

Main statistical findings

Structural profile

	Highest value added (1)		Largest number of persons employed (1)		Most specialised: share in non-financial business economy (%) (2)			
	Country	(EUR million)	(% of EU-27)	Country	(thousand)	(% of EU-27)	Country	Value added
1	United Kingdom	6 121	31.8	United Kingdom	114.6	23.6	Cyprus	1.1
2	Germany	4 095	21.2	Germany	63.6	13.1	United Kingdom	0.6
3	France	1 844	9.6	Spain	56.8	11.7	Greece	0.4
4	Spain	1 817	9.4	Italy	45.6	9.4	Estonia	0.4

Table 1: Activities of travel agencies and tour operators; tourist assistance activities n.e.c. (NACE Group 63.3). Structural profile: ranking of top five Member States in terms of value added and persons employed, 2006

There were approximately 78.2 thousand [enterprises](#) in the travel agencies activity (NACE Group 63.3) in the [EU-27](#) in 2006 and they [employed](#) a total of 484.7 thousand persons. Together these generated EUR 153.2 billion of [turnover](#) and EUR 19.3 billion of [value added](#). This sector accounted for 12.7% of the transport services (NACE Divisions 60 to 63) turnover, but just 4.8% of its value added, while its share of the transport services workforce was 5.5%.

The very different turnover and value added shares reflects the nature of this activity which is quite different from the other transport services, in that it often involves the purchase and resale of travel and accommodation services; as such this activity is similar to a distributive trades activity. The United Kingdom and Germany were by far the largest contributors to the wealth and employment generated by travel agencies in the EU-27 as together they accounted for 53.0% of the value added and 36.8% of the workforce. In value added terms these two Member States were also relatively specialised in the travel agencies sector, although not to the same extent as Cyprus (2005) which generated 1.1% of its non-financial business economy value added in this sector¹⁴⁹.

¹⁴⁹Bulgaria, Cyprus, Poland and Romania, 2005; Malta and the Netherlands, not available.

Expenditure and productivity

The travel agencies sector may be contrasted with the other transport services covered by the transport and storage sector in that its gross [tangible investment](#) expenditure was particularly low, just EUR 1.5 billion in the EU-27 in 2006. As such, this sector stood out from the other transport services as gross tangible investment was equivalent to 7.8% of value added, only just over one quarter of the average [investment rate](#) for transport services (28.5%).

An analysis of operating expenditure in 2006 also shows a particularly low share of [personnel costs](#) for the activities of travel agencies (8.1%) within the EU-27, again reflecting the high purchases of goods and services that are resold to customers. Average personnel costs and apparent [labour productivity](#) were also low, EUR 27.5 thousand per employee and EUR 39.8 thousand per person employed respectively. These two relatively low average values counterbalanced each other such that the [wage-adjusted labour productivity ratio](#) for the activities of travel agencies (144.7%) was almost identical to the transport services' average. Austria and Luxembourg both recorded wage adjusted labour productivity ratios below parity (100%), indicating that average personnel costs were higher than apparent labour productivity¹⁵⁰, while Germany was the only Member State to record a wage adjusted labour productivity ratio for travel agencies that was significantly above the average ratio for the non-financial business economy.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include Eurostat information society statistics.

Context

The transport and storage sector focuses on transport services provided to clients for hire and reward. When analysing transport traffic volumes (for example, tonnes of freight) as presented in this article, it is important to bear in mind that these include own account transport as well as transport services for hire and reward. This is particularly important in road transport where, for example, a manufacturer might collect materials or deliver own [output](#), rather than contracting a transport service enterprise to do this. Equally, the use of own vehicles (typically passenger cars) accounts for a very large part of passenger transport. Such own account transport does not contribute towards the statistics on the transport services sector.

EU transport policy is based upon the 2001 White paper '[European transport policy for 2010: time to decide](#)' and the 2006 mid-term review in the European Commission's communication ([COM\(2006\) 314](#)) 'Keep Europe moving – sustainable mobility for our continent'. In 2007 the European Commission adopted a communication ([COM\(2007\) 606](#)) on 'Keeping freight moving', to make rail freight more competitive, facilitate modernisation of ports, and review progress in the development of sea shipping.

Environmental issues remain of great importance to this sector, as transport is a major source of emissions and noise. In 2008 the European Commission put forward a package of measures related to road and rail transport referred to as 'Greening Transport'. This included a communication ([COM\(2008\) 433](#)) summarising the packages and initiatives planned for 2009, a strategy to internalise the cost of transport externalities, a proposal for a Directive on road tolls for lorries, and a communication on rail noise. The overall thrust of the package is to try to move towards more sustainable transport.

Travel agents act as retailers selling travel services or packaged trips to the customer. Traditionally, tour operators acted as wholesalers to travel agents, while more recently they have moved towards selling directly to customers. Tourist guides and tourist information services play a supporting role, offering information and services usually at the tourism destination. Like airlines, tour operators also faced trading difficulties in 2008: for example, the United Kingdom's third largest operator, XL leisure group (which also operated XL airways), declared bankruptcy in September 2008.

¹⁵⁰Cyprus and Poland, 2005; Malta, not available.

More than half of all individuals (aged 16 to 74 that use the Internet), made use of on-line services for travel and/or accommodation. This may include research or bookings, and may be directly with travel and accommodation providers, or with intermediaries.

Table 4b: Key indicators, travel agency, tour operator reservation service and related activities (NACE Division79), 2009 - Source: Eurostat (sbs_na_1a_se_r2)

Main statistical findings

Structural profile

There were 86 thousand enterprises operating within the travel agency and related services (Division79) sub-sector in the EU-27 in 2009. Together they employed 469 thousand persons, equivalent to 0.3% of the total workforce in the non-financial business economy (Sections B to J and L to N and Division95) and 3.9% of persons in administrative and support services (Section N). Travel agency and related services generated EUR21000 million of value added which was 0.4% of the non-financial business economy total or 6.0% of the added value for administrative and support services. As such, in both employment and value added terms, travel agency and related services were the smallest of the six NACE divisions that make-up administrative and support services. Given the nature of travel agency and related services it is not surprising to find that they had relatively high turnover, some EUR142000 million across the EU-27 in 2009, which was equivalent to 0.6% of the non-financial business economy total.

The somewhat higher share of non-financial business economy value added compared with employment for the travel agency and related services sector meant that the apparent labour productivity of EUR44 thousand per person employed in this sector in 2009 was slightly above the non-financial business economy average of EUR41.6 thousand and also much higher than the administrative and support services average of EUR29 thousand. Average personnel costs within the EU-27's travel agency and related services sector were just EUR100 per employee higher than the non-financial business economy average, as they stood at EUR30.1 thousand per employee in 2009, considerably above the average for administrative and support services (EUR20.9 thousand per employee). The wage-adjusted labour productivity ratio for EU-27 travel agency and related services in 2009 was 148.0%, somewhat higher than the non-financial business economy average (138.8%) or the administrative and support services average (139.1%).

The gross operating rate (the relation between the gross operating surplus and turnover) is one measure of operating profitability; it stood at 6.1% for the EU-27's travel agency and related services sector in 2009, which was less than two thirds of the non-financial business economy average (9.7%) and considerably lower than the administrative and support services average (15.2%). Indeed, the gross operating rate for travel agency and related services was the lowest among the six NACE divisions within administrative and support services.

Sectoral analysis

The travel agency and related services sector can be divided into two subsectors, the largest of which in the EU-27 – by far – was the travel agency and tour operator activities subsector (Group79.1). It accounted for 90.9% of sectoral value added in 2008 and for 87.4% of sectoral employment in 2009; the residual shares being attributed to other reservation services and related activities (Group79.9).

Given the relative weight of the travel agency and tour operator activities subsector there was little difference between it and the whole of the travel agency and related services sector for a range of productivity and profitability measures.

For apparent labour productivity, the latest information available shows that both subsectors recorded productivity levels that were close to the EU-27 non-financial business economy average, with persons employed in the travel agency and tour operator activities subsector generating on average EUR44 thousand of added value in 2008, while for other reservation services and related activities the corresponding ratio stood at EUR41 thousand in 2009. EU-27 average personnel costs for the travel agency and tour operator activities subsector were, at EUR30.0 thousand per employee in 2009, identical to the average for the whole of the non-financial business economy, while those for other reservation services and related activities subsector were some EUR2.3 thousand per employee higher. Wage-adjusted labour productivity ratios – which are constructed through dividing apparent labour productivity by average personnel costs – were also close to the non-financial business economy average. This was particularly true for the travel agency and tour operator activities subsector (145.0% in 2008), while the ratio was somewhat lower for other reservation services and related activities (127.9% in 2009).

The relatively low gross operating rate (6.0%) for the EU-27's travel agency and tour operator activities subsector in 2009 reflects, to some degree, the trading nature of these activities and the high volume of buying and reselling travel and tourism services. The gross operating rate for other reservation services and related activities (12.6%) was above the non-financial business economy average of 9.7%.

Country analysis

More than half of the EU-27's value added within the travel agency and related services sector in 2009 was generated in either the United Kingdom (26.5%) or Germany (24.7%); these figures reflect the high tourism demand in these two countries. The data also suggest that these two countries have relatively large enterprises in this sector, as there were less enterprises operating in Germany or the United Kingdom than in either Spain or Italy which in turn accounted for 9.3% and 6.0% of EU-27 value added.

The relative importance of travel agency and related services in terms of their contribution to non-financial business economy value added was highest in Cyprus, attaining a 1.0% share in 2009. This was much higher than in any of the other Member States for which data are available, as the second most specialised Member State was the United Kingdom, where 0.6% of non-financial business economy value added was generated in the travel agency and related services sector. At the other end of the range, there were three Member States where less than 0.2% of non-financial business economy value added was generated within the travel agency and related services sector – these were Romania, Poland and Hungary.

In employment terms, the travel agency and related services sector's workforce was less concentrated than for value added. There were as many as 82.9 thousand persons employed within travel agency and related services in the United Kingdom in 2009 (a 17.7% share of the EU-27 total). Germany had the second largest workforce (16.3% of the EU-27 total), while Spain (12.1%) and Italy (10.4%) also recorded double-digit shares; note that the information for France is based on the number of employees and not persons employed.

Most Member States reported wage-adjusted labour productivity ratios for travel agency and related services in 2009 that were below their national averages for the whole of the non-financial business economy. However, there were four countries – the two largest in terms of value added, the United Kingdom and Germany, as well as the Netherlands and Slovakia – that did not follow this pattern; all four of these recorded wage-adjusted labour productivity ratios that were over 170% as did Romania and Latvia. The highest wage-adjusted labour productivity ratio was recorded for Germany (228.2%). At the other end of the range, the lowest ratios – falling below 100% – were recorded in Slovenia, Hungary and Italy, showing that, on average, the added value generated per person employed did not cover average personnel costs per employee.

Gross operating rates for travel agency and related services were generally relatively low across the Member States – and were situated below non-financial business economy averages in 2009 for all of the Member States except for Cyprus and Germany. These were the only two countries where this measure of operating profitability rose into double-digits, reaching 23.2% and 15.2% respectively. In contrast, the gross operating rate for travel agency and related services fell below 2% in France, Austria, Slovenia, Portugal and Hungary (where the lowest rate was recorded, 0.5%).

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the travel agency and tour operator reservation and related service activities sector in the EU-27, as covered by NACE Rev.2 Division79. This division includes the activity of agencies, primarily engaged in selling travel, tour, transportation and accommodation services and the activity of arranging and assembling tours; other travel-related services are also included. Travel agencies activities are primarily engaged in selling travel, tour, transportation and accommodation services on a wholesale or retail basis to the general public and commercial clients. Tour operators arrange and assemble tours that are sold through travel agencies or directly by tour operators. The tours may include any or all of the following: transportation, accommodation, food, and visits to museums, historical or cultural sites, theatrical, musical or sporting events. Other reservation services and related activities include: marketing and promoting of services for conventions and visitors by providing information and assistance to organisations to locate accommodation, convention centres and entertainment venues; tourist guide services; condominium time-share exchange services; travel-related reservation services; ticket sales for theatrical, sports and all other amusement and entertainment events.

This NACE division is composed of two groups:

- travel agency and tour operator activities (Group79.1);
- other reservation service and related activities (Group79.9).

Note that the information presented in this article does not cover [accommodation and food service activities](#) , such as the running of hotels, campsites, restaurants, bars or cafés, but is rather restricted to selling, organising and reserving services that are sourced from these (and other) providers.

Table 2b: Key indicators, veterinary activities (NACE Division 75), 2009 - Source: Eurostat (sbs_na_1a_se_r2)

Main statistical findings

Structural profile

The veterinary services sector (Division 75) in the EU-27 comprised 65 thousand enterprises in 2009, employed 186 thousand persons and created EUR6500 million of value added. This sector represented approximately 0.1% of the non-financial business economy (Sections B to J and L to N and Division 95) in terms of employment and value added. Its contribution to all professional, scientific and technical activities (Section M) was 1.7% of the workforce and 1.2% of value added. Within the EU-27, based on these two measures, the veterinary services sector was the smallest among the seven NACE divisions within professional, scientific and technical activities.

The veterinary services sector combined the lowest EU-27 apparent labour productivity (EUR35 thousand per person employed) and average personnel costs (EUR22.9 thousand per employee) among the NACE divisions within professional, scientific and technical activities in 2009; for both of these ratios the values for the veterinary services sector were below the non-financial business economy averages (EUR41.6 thousand per person employed and EUR30.0 thousand per employee). The particularly low average personnel costs boosted the wage-adjusted labour productivity ratio for the EU-27's veterinary services sector to 151.8% in 2009. This was the only NACE division among the EU-27's professional, scientific and technical activities where the wage-adjusted labour productivity ratio exceeded the non-financial business economy average (138.8%). Alongside relatively high wage-adjusted labour productivity, the EU-27's veterinary services sector recorded a gross operating rate of 28.2% in 2009, which was the second highest rate for any NACE division within professional, scientific and technical activities and was nearly three times as high as the non-financial business economy average (9.7%).

Country analysis

In 2009, close to one quarter (24.6%) of EU-27 value added in veterinary services was contributed by the United Kingdom, with Germany (20.8%) and France (20.6%) each accounting for approximately one fifth of the total. In value added terms, the most specialised Member States in veterinary services in 2009 were the United Kingdom, Ireland, Slovenia, France and Belgium, where this sector contributed 0.2% of non-financial business economy value added; a similar contribution was also recorded for Croatia.

Belgium, Germany, Austria and Slovakia recorded wage-adjusted labour productivity ratios for the veterinary services sector in excess of 200% in 2009; the ratio for veterinary services for these three Member States, as well as for the Netherlands and Finland, was above national non-financial business economy averages (Belgium, not

available). In contrast, Latvia, Lithuania and Sweden reported that their wage-adjusted labour productivity ratios for veterinary services failed to reach 100% in 2009.

The relatively high gross operating rate observed for the veterinary services sector in the EU-27 in 2009 was also evident in nearly all Member States, as Romania was the only country where the gross operating rate for the veterinary services sector was below the average rate for the whole of the non-financial business economy. The highest gross operating rates observed for veterinary services in 2009 were 51.9% in Italy and 46.2% in Belgium; in both of these Member States this was the highest gross operating rate recorded in 2009 among all of the non-financial business economy NACE divisions.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the veterinary services sector in the EU, as covered by NACE Rev.2 Division 75. This division includes the provision of animal healthcare and control activities for farm animals or pet animals. These activities are carried out by qualified veterinarians in veterinary hospitals as well as when visiting farms, kennels or homes, in own consulting and surgery rooms, or elsewhere. The veterinary services sector also covers animal ambulance activities.

This division contains one group and one class only and so there is no analysis of subsectors in this article.

Warehousing and transport logistics statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers warehousing and transport logistics statistics, corresponding to NACE Groups 63.1, 63.2 and 63.4, which are part of the [transport and storage](#) sector. The article includes information on auxiliary and supporting transport activities, which are a diverse range of services including:

- support services for all modes of transport, such as baggage and cargo handling, storage/warehousing and freight forwarding/brokerage;
- the operation of terminals (rail and bus stations, ports and airports);
- infrastructure (notably for inland waterways, railways, roads, tunnels and bridges);
- navigational services (notably for air and water transport);
- towing, berthing and parking services (including car parks).

Note that these services may be provided by enterprises with their principal activity in warehousing and transport support activities or by enterprises classified to other activities, often transporters or wholesalers (in which case they will not be included in the statistics of this article). Travel agencies are covered in [the article on travel agencies statistics](#).

Main statistical findings

Structural profile

Warehousing and transport support activities (NACE Groups 63.1, 63.2 and 63.4) constitute a significant part of the EU-27's transport services sector, with 109.6 thousand enterprises which collectively employed 2.2 million persons in 2006. Paid employees accounted for 95.7% of all persons employed in this sector, well above the transport services average (88.0%). The workforce generated EUR 384.3 billion of turnover in 2006, resulting in EUR 139.8 billion of value added. As such, the warehousing and transport support activities sector generated 34.9% of transport services (NACE Divisions 60 to 63) value added and employed 24.7% of the workforce. By both of these measures it was the second largest transport services activity (among the activities presented in

the sub-sectors of the transport and storage sector).

In value added and employment terms Germany dominated the warehousing and transport support activities sector, contributing between one quarter and one fifth of both value added and employment. In relative terms, Estonia and Latvia were the most specialised in this sector, as warehousing and transport support activities contributed 6.0% and 4.2% respectively of the **non-financial business economy**'s value added in these Member States¹⁵¹. At the other end of the range, warehousing and transport support activities contributed only around 1% to non-financial business economy value added in Poland (2005), Luxembourg, Slovakia and the Czech Republic.

Focus on transport networks

While the transport services described in most of the other sub-sectors of the transport and storage sector use transport infrastructure, infrastructure management enterprises are considered as supporting transport activities (within NACE Group 63.2).

In 2005, rail transport services relied on a network encompassing approximately 215.5 thousand km of lines across the EU-27. In density terms, in other words the length of railway line in relation to the area of a country, this was the equivalent of 50 m of track per square kilometre. The Czech Republic, Belgium and Germany had the most dense rail networks, all¹⁵² in excess of 100 m of railway line per square kilometre. Cyprus and Malta had no rail network, and the least dense networks were unsurprisingly found in Finland, Estonia and Sweden (the three Member States with the lowest population densities), as well as in Greece.

Road transport services could count on approximately 59.5 thousand km of motorways in the EU-27 in 2004. While Germany (12.0 thousand km), France (10.4 thousand km) and Spain (10.3 thousand km) had by far the most extensive motorway networks, accounting together for more than half (55%) of the EU-27 total in 2004, the Netherlands and Belgium had the highest densities of motorways. Note that there was no motorway network in Latvia or Malta. A low density of motorway networks was also recorded in the three least densely populated Member States, as well as in Poland and Ireland.

Inland waterways used for transport constituted a network in excess of 38.0 thousand km in the EU-27 in 2004: note that when such waterways constitute a border between two countries they are counted by both countries. Among the Member States, Finland, Germany and the Netherlands had the longest inland waterways on their territory.

Focus on ports and airports

Seven of the ten largest EU-27 sea ports in 2007 were on the North Sea. Rotterdam (the Netherlands) was the largest of all, with 374.2 million tonnes of freight loaded and unloaded in 2007, more than twice the volume of the next largest port, Antwerp (Belgium) with 165.5 million tonnes.

In 2007, the EU-27's largest airport in passenger terms was London Heathrow (the United Kingdom) with 67.9 million passengers. As regards freight traffic, the largest airport in the EU-27 was Frankfurt (Germany) with 2.2 million tonnes of loaded and unloaded freight and mail in 2007.

Expenditure and productivity

Tangible investment by the warehousing and transport support activities sector in the EU-27 was valued at EUR 48.5 billion in 2006, equivalent to 42.5% of the transport services total. This high level of investment resulted in an **investment rate** of 34.7% in 2006, well above the transport services average and close to double the non-financial business economy average (18.4%). Slovakia, Slovenia and Hungary all recorded investment rates in excess of 200% in this sector in 2006, between 4.4 and 7.4 times as high as the average rates in their national non-financial business economies.

¹⁵¹Bulgaria, Cyprus, Poland and Romania, 2005; Malta and the Netherlands, not available.

¹⁵²Recent data is not available for Luxembourg, but older data indicates a high density.

The share of [personnel costs](#) (22.4%) in operating expenditure recorded by the EU-27's warehousing and transport support activities sector was almost identical to the average recorded for all transport services. In contrast, average personnel costs in this sector were above average, reaching EUR 35.8 thousand per employee in the EU-27 in 2006. Nevertheless, above average apparent [labour productivity](#) (EUR 64.0 thousand per person employed) more than compensated for the high average personnel costs, and this was reflected in the ratio of [wage-adjusted labour productivity](#) which was 178.8% in the EU-27, well above the transport services and non-financial business economy averages.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include Eurostat statistics for transport, inland waterways transport, maritime transport and air transport.

Context

The transport and storage sector focuses on transport services provided to clients for hire and reward. When analysing transport traffic volumes (for example, tonnes of freight) as presented in this article, it is important to bear in mind that these include own account transport as well as transport services for hire and reward. This is particularly important in road transport where, for example, a manufacturer might collect materials or deliver own [output](#), rather than contracting a transport service enterprise to do this. Equally, the use of own vehicles (typically passenger cars) accounts for a very large part of passenger transport. Such own account transport does not contribute towards the statistics on the transport services sector.

EU transport policy is based upon the 2001 White paper '[European transport policy for 2010: time to decide](#)' and the 2006 mid-term review in the European Commission's communication ([COM\(2006\) 314](#)) 'Keep Europe moving – sustainable mobility for our continent'. In 2007 the European Commission adopted a communication ([COM\(2007\) 606](#)) on 'Keeping freight moving', to make rail freight more competitive, facilitate modernisation of ports, and review progress in the development of sea shipping.

Environmental issues remain of great importance to this sector, as transport is a major source of emissions and noise. In 2008 the European Commission put forward a package of measures related to road and rail transport referred to as 'Greening Transport'. This included a communication ([COM\(2008\) 433](#)) summarising the packages and initiatives planned for 2009, a strategy to internalise the cost of transport externalities, a proposal for a Directive on road tolls for lorries, and a communication on rail noise. The overall thrust of the package is to try to move towards more sustainable transport.

In June 2008, the European Commission adopted a communication ([COM\(2008\) 389](#)) on the further development of the so-called 'Single European Sky' (legislation adopted in 2004), focussing on safety, capacity, efficiency and the environment in the context of air traffic control.

In October 2007, the European Commission adopted a communication ([COM\(2007\) 616](#)) on a ports policy, focussing on capacity, freedom of access, competition, flexible employment and the environment.

Table 4b: Key indicators, warehousing and support activities for transportation (NACE Division 52), 2009 - Source: Eurostat (sbs_na_1a_se_r2)

Structural profile

There were 122 thousand enterprises operating within the EU-27's warehousing and transport support services (Division52) sector in 2009. Together they employed 2.38 million persons, equivalent to 1.8% of the non-financial business economy (SectionsB to J and L to N and Division95) workforce and almost a quarter (22.5%) of those employed in transportation and storage services (SectionH). They generated EUR141297 million of value added which was 2.5% of the non-financial business economy total and almost one third (32.4%) of the transportation and storage total.

With its higher share of transportation and storage value added (compared with its share of the workforce), the apparent labour productivity of the EU-27's warehousing and transport support services sector in 2009 was EUR59 thousand per person employed, considerably above the non-financial business economy average of EUR41.6 thousand or the transportation and storage average of EUR41 thousand.

Average personnel costs within the EU-27's warehousing and transport support services sector were, at EUR35.8 thousand per employee in 2009, also above the non-financial business economy average (EUR30.0 thousand) and the average for the whole of transportation and storage services (EUR31.2 thousand); although the differences were relatively modest. As a result, the wage-adjusted labour productivity ratio, which shows the extent to which value added per person employed covers average personnel costs per employee, stood at 165.9% for the EU-27's warehousing and transport support services sector in 2009, compared with a non-financial business economy average of 138.8% and a transportation and storage average of 132.1%.

The gross operating rate (which measures the relation between the gross operating surplus and turnover) is one measure of operating profitability; it stood at 15.6% for the EU-27's warehousing and transport support services sector in 2009, about 60% higher than the non-financial business economy average of 9.7% and also higher than the transportation and storage average of 12.2%.

Sectoral analysis

The warehousing and transport support services sector is divided into two Groups, the larger of these – using each of the main economic measures – was transportation support activities (Group52.2). In terms of its share of enterprises, persons employed and value added, the EU-27's transportation support activities subsector accounted for a share between 80% and 90% of the sectoral total in warehousing and transport support services. There were 107.3 thousand enterprises within the EU-27's transportation support activities subsector, which together employed an estimated two million persons, and generated added value of EUR120000 million in 2009. The warehousing and storage subsector (Group52.1) was much smaller and was made-up of 14.3 thousand enterprises.

EU-27 apparent labour productivity in the transportation support activities subsector was EUR60 thousand per person employed in 2009, which was some EUR9 thousand higher than the corresponding ratio for warehousing and storage. The gross operating rates of both subsectors were relatively high, standing at 16% for support activities for transportation and 15% for warehousing and storage, compared with a non-financial business economy average of 9.7% and a transportation and storage average of 12.2%.

Country analysis

Germany generated EUR31131 million of value added in the warehousing and transport support services sector in 2009, equivalent to 22.0% of the EU-27 total. There were also relatively high shares of the EU-27 total for France (15.7%) and the United Kingdom (15.1%), while Italy (11.1%) was the only other country to record a double-digit share. Germany had a slightly higher share of the warehousing and transport support services sector's workforce, 23.1% of the EU-27 total in 2009.

At a more disaggregated level, Germany also made the largest contribution to EU-27 value added in the transportation support activities subsector (23.7%), while the United Kingdom had the highest level of value added (EUR4442 million) for the warehousing and storage. However, the Baltic Member States had the highest degree of specialisation for warehousing and transport support services: 7.5% of Latvian non-financial business economy value added was generated by transportation support activities in 2009, while 1.0% of Estonian non-financial business economy value added came from the warehousing and storage subsector.

Most Member States reported relatively high wage-adjusted labour productivity ratios for warehousing and transport support services in 2009; only Slovakia (82.8%) had a ratio below 100%. The highest wage-adjusted labour productivity ratios were recorded in Estonia (251.5%), Portugal (244.6%) and Latvia (204.4%). The highest gross operating rates for warehousing and transport support services in 2009 were in Cyprus (30.6%), Portugal (27.1%) and the United Kingdom (24.3%). There were only five Member States recording a gross operating rate that was below 10%, they included Ireland, Finland, Sweden, Luxembourg and Slovakia (where the only negative rate was posted, -4.4%).

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the warehousing and transport support services sector in the EU, as covered by NACE Rev.2 Division52.

The warehousing and storage activity includes the operation of storage and warehouse facilities for all kinds of goods, for example in grain silos, general or refrigerated warehouses, storage tanks and so on, as well as in foreign trade zones.

Support activities for transportation includes activities supporting the transport of passengers or freight, such as the operation of parts of the transport infrastructure or activities related to handling freight immediately before or after transport or between transport segments. The operation and maintenance of all transport facilities is also included. Examples of transport infrastructure include: airports, harbours, tunnels, bridges, and so on. Also included in incidental service activities are: towing and road side assistance and liquefaction of gas for transportation purposes; navigation, pilotage and berthing activities, lighterage, salvage activities and light-house activities; ground service activities on airfields and fire fighting and fire-prevention services at airports. Other transport support activities include for example freight forwarding and brokerage as well as activities of customs agents.

This NACE division is composed of two groups:

- warehousing and storage (Group52.1);
- support activities for transportation (Group52.2).

Self-storage facilities and the rental of vacant space (part of Division68, covered within [real estate activities](#)), as well as the activities of travel agencies and tour operators and related activities (Division79, [travel agency, tour operator and other reservation service and related activities](#)) are excluded from the statistics presented in this article.

Table 4b: Key indicators, waste collection, treatment and disposal activities; materials recovery (NACE Division38), 2009 - Source: Eurostat (sbs_na_ind_r2)

Main statistical findings

Structural profile

The EU-27's waste and materials recovery (Division38) sector comprised 36 thousand enterprises in 2009, around 0.2% of the non-financial business economy (Sections B to J and L to N and Division95) enterprise population. These enterprises employed 735 thousand persons, equivalent to 0.5% of the total number of persons employed in the non-financial business economy and nearly three fifths (57.9%) of the water supply, sewerage, waste management and remediation activities (Section E) workforce. The value added of the EU-27's waste and materials recovery sector reached EUR35771 million in 2009 which was 0.6% of the non-financial business economy total and close to half (45.5%) of the water supply, sewerage, waste management and remediation activities total.

The waste and materials recovery sector's apparent labour productivity was EUR49 thousand per person employed in the EU-27 in 2009, distinctly higher than the non-financial business economy average (EUR41.6 thousand per person employed), but at the same time well below the water supply, sewerage, waste management and remediation activities average (EUR62 thousand per person employed). Nevertheless, average personnel costs within the EU-27's waste and materials recovery sector were EUR30.5 thousand per employee, in line with the EUR30.0 thousand per employee average for the whole of the non-financial business economy and the EUR31.5 thousand per employee average for water supply, sewerage, waste management and remediation activities. The wage-adjusted labour productivity ratio combines the two previous indicators and shows the extent to which value added per person employed covers average personnel costs per employee: as a consequence of the typical level of average personnel costs in the EU-27's waste and materials recovery sector in 2009 this ratio was most influenced by the relative level of the apparent labour productivity. The wage-adjusted labour productivity ratio for the EU-27's waste and materials recovery sector was 159.2% in 2009, between the non-financial business economy average of 138.8% and the water supply, sewerage, waste management and remediation activities average of 196.8%. In a similar manner, the 13.0% ratio of gross operating surplus to turnover (known as the gross operating rate) for the EU-27's waste and materials recovery sector in 2009 was above the non-financial business economy average (9.7%) but below the water supply, sewerage, waste management and remediation activities average (20.9%).

Sectoral analysis

In terms of the number of enterprises the EU-27's materials recovery subsector (Group38.3) was the largest of the three subsectors that form the waste and materials recovery sector, with 16.4 thousand enterprises in 2009.

This was followed by waste collection (Group38.1) with 14.9 thousand enterprises, while waste treatment and disposal (Group38.2) had by far the smallest enterprise population (5.2 thousand). However, based on employment or value added the largest subsector by far was waste collection, while the materials recovery subsector was slightly smaller than waste treatment and disposal – see Figure 1.

The relatively high apparent labour productivity figure for the whole of the EU-27's waste and materials recovery sector in 2009 was pulled upwards by the waste treatment and disposal subsector where an average of EUR70 thousand of value was added per person employed. For the two other subsectors apparent labour productivity was lower, particularly for waste collection where an average of EUR40 thousand per person employed was observed, which was slightly below the non-financial business economy average. The range in average personnel costs per employee was also quite large, from EUR28.5 thousand for materials recovery and EUR29.0 thousand for waste collection to EUR37.5 thousand for waste treatment and disposal.

The particularly high apparent labour productivity for the EU-27's waste treatment and disposal subsector boosted its wage-adjusted labour productivity ratio to 191.7% in 2009. For materials recovery, the wage-adjusted labour productivity ratio was 162.6%, while for waste collection the ratio was 138.1%, in line with the non-financial business economy average (138.8%). In terms of profitability (based on the gross operating rate), the waste treatment and disposal subsector also had the highest value (20.0%), while the materials recovery subsector was the only one to record a rate (8.1%) below the non-financial business economy average (9.7%).

Country analysis

Among the Member States the largest workforce in the waste and materials recovery sector in 2009 was in Italy (134.5 thousand persons), equivalent to 18.3% of the EU-27 workforce. Double-digit shares of the EU-27 total were also recorded in Germany (13.6%), France (12.3%, based on paid employees) and the United Kingdom (11.4%). In employment terms, Romania was the most specialised of the Member States in the waste and materials recovery sector, as 1.1% of the Romanian non-financial business economy workforce were employed in this sector in 2009. The Czech Republic, Slovakia and Italy were also relatively highly specialised in employment terms, as in each of these Member States 0.9% of the non-financial business economy workforce were employed in the waste and materials recovery sector; Cyprus (0.2%) and Spain (0.3%) were the least specialised Member States and Switzerland (0.3%) was also relatively unspecialised in employment terms.

In value added terms, Italy was the largest Member State (note that no data is available for Germany) in the waste and materials recovery sector in 2009. Italy was also the most specialised country, with 1.2% of value added in the Italian non-financial business economy being generated by the waste and materials recovery sector. Both Latvia and Slovakia were also particularly specialised in this sector as it contributed more than 1% of their non-financial business economy value added. The least specialised Member States in the waste and materials recovery sector, in value added terms, were Cyprus (0.3%) and Spain (0.4%), while Norway (0.3%) and Switzerland (0.4%) also recorded a low share of non-financial business economy value added in this sector.

A different Member State was largest in each of the three subsectors in both employment and value added terms in 2009 (as noted above there is no German value added data available). Italy had the largest waste collection subsector in terms of employment and value added. For the waste treatment and disposal subsector France had the highest value added, although both Germany and the United Kingdom had larger workforces. In contrast, the United Kingdom had the highest level of value added for the materials recovery subsector, while both France and Italy had larger workforces.

Most Member States recorded a higher wage-adjusted labour productivity ratio for the waste and materials recovery sector in 2009 than they did for their non-financial business economy as a whole. The main exception to this pattern was Ireland where the wage-adjusted labour productivity ratio for the waste and materials recovery sector was 154.0%, some 26.8 percentage points below the Irish non-financial business economy average; Romania, the Czech Republic and Slovenia also recorded wage-adjusted labour productivity ratios in this sector that were slightly below their national averages. The highest wage-adjusted labour productivity ratios in the waste and materials recovery sector in 2009 were recorded in Latvia (265.9%) and Cyprus (236.8%) and these were also considerably higher than the non-financial business economy averages in these Member States. A similar situation was observed for the gross operating rate, with Ireland and Romania the only Member States recording rates for waste and materials recovery that were below national non-financial business economy averages, while the highest rates were posted in Latvia, Slovakia and Cyprus.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the waste and materials recovery sector in the EU, as covered by NACE Rev.2 Division38. This division includes the collection, treatment, and disposal of waste materials, including the operation of materials recovery facilities (in other words, those that sort recoverable materials from a waste stream). Both hazardous and non-hazardous waste are covered: the former includes explosive, oxidising, flammable, toxic, irritant, harmful, carcinogenic, corrosive, infectious or other substances and preparations harmful for human health and environment.

Waste collection includes the collection from households, businesses and public places of waste. Its collection may also entail identification, treatment, packaging and labelling of waste for the purposes of transport. The operation of waste transfer facilities is also included.

Waste treatment concerns treatment of waste prior to its disposal. Disposal includes dumping of refuse on land or in water, burial or ploughing-under of refuse, incineration or combustion; it also includes storage of radioactive nuclear waste. Energy recovery resulting from the waste incineration process is also included.

Materials recovery includes the dismantling of all types of wrecks (automobiles, ships, computers, televisions and other equipment) for materials recovery (rather than to remove reusable parts) and the recovery of sorted materials. Recovery of sorted materials involves the processing of metal and non-metal waste and scrap and articles into secondary raw materials. The recovery of materials from waste streams is also included in the form of: separating and sorting recoverable materials from non-hazardous waste streams (in other words, general rubbish); separating and sorting of commingled recoverable materials, such as paper, plastics, used beverage cans and metals, into distinct categories. Examples of the mechanical or chemical transformation processes that are undertaken include: mechanical crushing, mechanical reduction, shredding, cutting, pressing, pellet production, cleaning, melting, grinding and composting.

This NACE division is composed of three groups:

- waste collection (Group38.1);
- waste treatment and disposal (Group38.2);
- materials recovery (Group38.3).

The information presented in this article excludes the treatment and disposal of waste water, as covered by [water collection, treatment and supply](#) (Division36) and [sewerage](#) (Division37) as well as the remediation and clean-up of contaminated buildings, mine sites, soil and ground water, for example, through asbestos removal (as covered by [remediation and other waste management services](#) , Division39).

Water collection, treatment and supply statistics - NACE Rev. 2

Data from April 2012. Most recent data: Further Eurostat information, Main tables and Database .

This article presents an overview of statistics for the water collection, treatment and supply sector (hereafter referred to as the water supply sector) in the [European Union \(EU\)](#) , as covered by [NACE Rev.2 Division36](#). It should be noted that some water, particularly when used in production processes, does not come from the public water supply system, but rather is extracted directly from its source. Among the key issues that affect this sector are pricing and the metering of water use in the context of the efficient use of water resources, and also the costs of water services.

Main statistical findings

Structural profile

The number of enterprises classified to the water supply sector (Division36) in the EU-27 in 2009 was 9.7 thousand. Employment in this sector in 2008 was 370 thousand persons and value added was EUR29921 million. As such, in 2008 this sector employed 0.3% of the **non-financial business economy** (Sections B to J and L to N and Division95) workforce and 29.2% of the **water supply, sewerage, waste management and remediation activities** (Section E) workforce.

The **apparent labour productivity** of the EU-27's water supply sector in 2008 was relatively high, around

EUR80 thousand per person employed. Bearing this in mind, [average personnel costs](#) were quite modest, at EUR32.5 thousand per employee in 2009 compared with an average of EUR30.0 thousand per employee for the whole of the non-financial business economy and an average of EUR31.5 thousand per employee for water supply, sewerage, waste management and remediation activities.

The [gross operating rate](#) (the relation between the [gross operating surplus](#) and [turnover](#)) in the EU-27's water supply sector was relatively high, at 28.5% in 2008. For comparison, the equivalent rate for the non-financial business economy average in 2009 was 9.7%. It should be noted that this measure does not take account of depreciation or financial expenditure which are typically high in capital-intensive activities such as water supply with its extensive network infrastructure.

Country analysis

The organisation of the water supply sector takes many different forms, with state-owned, private and mutual enterprises, as well as municipalities involved in terms of the ownership and/or operation of infrastructure. As a result, the number of enterprises classified to the water supply sector and their size varies greatly between Member States reflecting whether or not this is a service provided by a large number of local suppliers or a relatively small number of regional or national suppliers. This diversity can be illustrated by an analysis of the average number of persons employed per enterprise, which ranged from less than 5 in Austria (4.4), Finland (3.8) and Denmark (1.5, 2008 data) to more than 200 in the Netherlands (204.5), Bulgaria (216.1), the United Kingdom (271.2, 2008 data) and Slovakia (395.0).

In employment terms, there were seven Member States that reported relatively large water supply sector workforces, ranging from just under 30 thousand persons in Italy and Poland, through 33 thousand in Romania, to more than 35 thousand in France (number of employees), Germany, Spain and the United Kingdom (2008 data). In value added terms, the United Kingdom stood out, with EUR9371 million in 2009; while the United Kingdom's share of EU-27 value added was 33.4% in 2008.

The relative importance of the water supply sector was highest, in value added terms, in Slovakia, the United Kingdom and Estonia where it accounted for 1.1% of non-financial business economy value added in 2009. The least specialised Member States, by this measure, were Luxembourg, Denmark, Sweden and Ireland where the water supply sector contributed less than 0.2% of non-financial business economy value added, as was the case in Switzerland and Norway.

Several Member States recorded particularly high [wage-adjusted labour productivity ratios](#) for the water supply sector in 2009. For example, Denmark recorded a wage-adjusted labour productivity ratio of 422.0%, compared with 146.0% for the Danish non-financial business economy as a whole; wage-adjusted labour productivity rates in the water supply sector that were more than 100 percentage points above national averages were also recorded in Estonia, Finland, Cyprus, the Netherlands, Sweden and Austria. In contrast, Ireland recorded a particularly low wage-adjusted labour productivity ratio for the water supply sector, 84.0%, indicating that apparent labour productivity per person employed was lower than average personnel costs per employee.

In terms of the gross operating rate, the high level recorded for the EU-27 was observed in nearly all Member States: the exceptions were Ireland where this measure of profitability was negative (-2.9%) and France where the next lowest rate was observed (5.7%) – these were the only Member States where the gross operating rate recorded for the water supply sector was below the national non-financial business economy average. Exceptionally high gross operating rates were recorded in the United Kingdom (57.6%), Estonia (54.8%) and Finland (43.0%); for Estonia and Finland these values marked the highest gross operating rates recorded for any of the non-financial business economy NACE divisions in 2009.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the water collection, treatment and supply sector in the EU, as covered by NACE Rev.2 Division36. This division includes the collection, treatment and distribution of water for domestic and industrial needs. This activity includes the collection of water from rivers, lakes, wells and so on, the collection of rain water, the purification of water for water supply purposes, the treatment of water for industrial and other purposes, the desalting of sea or ground water to produce water as the principal product of interest, the distribution of water through mains, by trucks or other means and the operation of irrigation canals.

This division contains one group and one class only and so there is no analysis of subsectors in this article.

The information that is presented in this article excludes the operation of irrigation equipment for agricultural purposes (which is part of crop and animal production, hunting and related service activities, Division01). It also excludes the treatment of wastewater in order to prevent pollution (part of [sewerage](#) , Division37) and the (long-distance) transport of water via pipelines (part of the [land transport and transport via pipelines](#) sector, Division49).

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

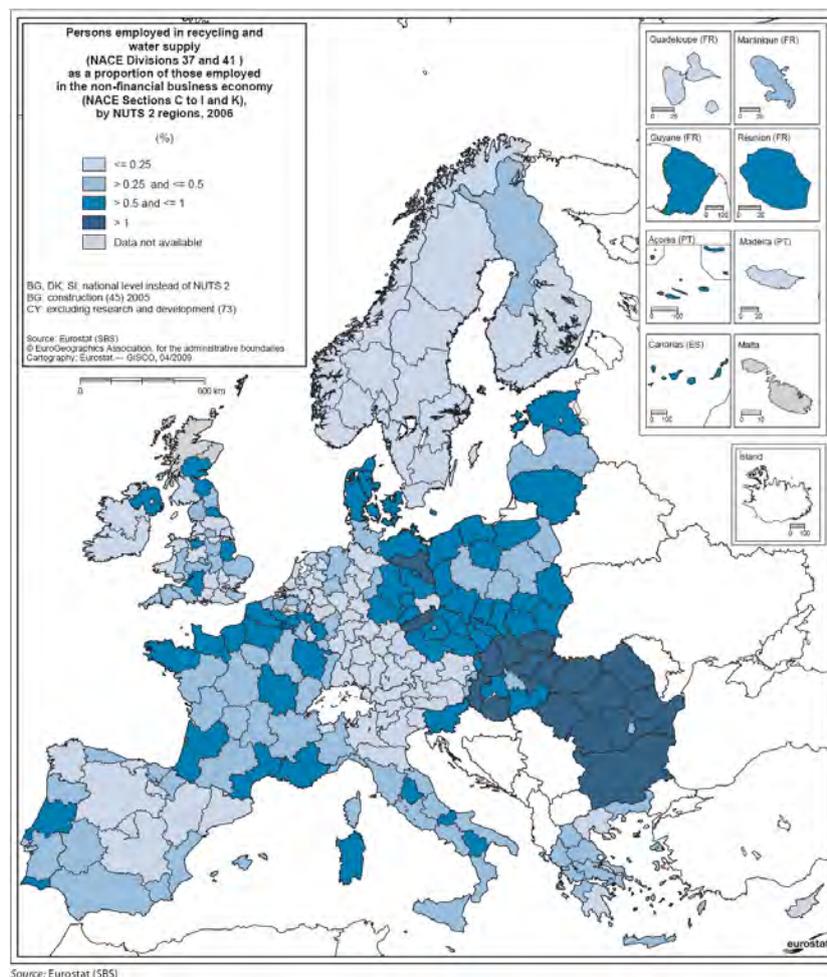

This article introduces a [set of statistical articles](#) which analyse the structure, development and characteristics of the economic activities in the water supply and recycling sector in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), this sector covers NACE Divisions 37 and 41, and its activities are treated in more depth in two further articles which cover:

	Enterprises		Turnover		Value added		Persons employed	
	(% of thousand)	(% of total)	(EUR million)	(% of total)	(EUR million)	(% of total)	(thousand)	(% of total)
Water supply and recycling	24.7	100.0	90 876	100.0	31 371	100.0	521.2	100.0
Water supply	9.0	36.4	47 219	52.0	23 264	74.2	370.7	71.1
Recycling	15.7	63.6	43 658	48.0	8 107	25.8	150.5	28.9

Table 4: Recycling (NACE Division 37). Main indicators, 2006 (1)

- [Recycling of waste and scrap](#) (NACE Division 37)
- [Water supply](#) (NACE Division 41), which does not cover the collection and treatment of sewage and other waste (NACE Classes 90.01 and 90.02).

Main statistical findings

Structural profile

There were 24.7 thousand [enterprises](#) with water supply or recycling (NACE Divisions 41 and 37) as their main activity within the [EU-27](#) in 2006, which together employed 521.2 thousand persons. Paid employees represented a 97.3% share of all persons employed in the EU-27's water supply and recycling sector in 2006, above the [non-financial business economy](#) average (NACE Sections C to I and K) of 86.5%. This workforce was equivalent to 0.4% of the non-financial business economy's total workforce in the EU-27, a share that was slightly less than the 0.6% share of [value added](#) that this sector generated from a total value added of EUR 31.4 billion. In terms of value added and employment this was the smallest of all of the industrial structural business statistics sectors, and the second smallest among the non-financial business economy sectors, larger only than research and development activities. Recycling (NACE Division 37) accounted for around one quarter of the value added in this sector and a slightly larger share of [employment](#), while water supply (NACE Division 41) accounted for the remainder.

The United Kingdom and Germany had the highest levels of [output](#) among the Member States in this sector, with 23.3% and 20.0% shares of EU-27 value added respectively, while France (14.0%) was the only other Member State with a double-digit share. However, France had the largest workforce, 65.1 thousand persons employed, equivalent to 12.5% of the EU-27 total, followed by Germany (11.7%), Poland (10.9%, 2005) and Romania (9.4%), while the United Kingdom's 9.0% share of the workforce was less than half its value added share. In both value added and employment terms this sector's contribution to the non-financial business economy was highest in Slovakia, Romania and Bulgaria (both 2005)¹⁵³.

Regional specialisation in the water supply and recycling sector in employment terms is shown in the map, although statistical confidentiality limits the exact data availability. Almost all of the regions most specialised in recycling and water supply were in Member States that joined the EU in 2004 or 2007, particularly in Hungary, Romania, Slovakia, the Czech Republic and Bulgaria, the latter treated as one region in the map, the only other region being in Germany.

¹⁵³Bulgaria, Poland and Romania, 2005; Ireland, Greece, Cyprus, Malta and the Netherlands, incomplete or not available.

The [index of production](#) for recycling for the EU-27 is available since 2000 and shows that output grew most years, contracting strongly in 2001 and more gently in 2005. Despite these two negative annual rates of change, over the period 2000 to 2007 the recycling activity saw its output expand at an average annual rate of 4.2%, far ahead of the industrial (NACE Sections C to E) average over the same period (1.6%). As such, based on the production index, this was the fastest growing industrial NACE division during this period. Growth was particularly strong in 2006 and 2007, reaching 11.1% and 9.5%. This performance was confirmed by the [employment index](#) which grew by 5.8% per year on average over the same seven year period, and by 4.7% per year over the ten years to 2007: only six industrial NACE divisions recorded overall employment growth during this ten-year period and recycling had by far the fastest growth rate among them.

The employment index for water supply displayed a similar profile to that for industry as a whole, but with a slower rate of decline: for water supply the index fell by 0.2% per year on average between 1997 and 2007, compared with a fall of 1.2% for industry as a whole.

A size class analysis of water supply and recycling in the EU-27

indicates very different structures in these subsectors. In recycling, [small enterprises](#) (with between 10 and 49 persons employed) and [medium-sized enterprises](#) (with between 50 and 249 persons employed) collectively employed 65.4% of the workforce in the EU-27 in 2006, well above the non-financial business economy average of 37.7%. In fact, the 35.0% share of small enterprises was the second highest employment share recorded by small enterprises among any of the NACE divisions of the non-financial business economy¹⁵⁴. In contrast, in water supply, large enterprises (with more than 250 persons employed) were responsible for more than three fifths of employment in the EU-27 and around two thirds of value added.

Employment characteristics

The [labour force](#) of the EU-27's water supply and recycling sector was characterised by a high proportion of male employment, 78.4% in 2007: this was 13.4 percentage points higher than the non-financial business economy average. The two subsectors recorded fairly similar proportions of the workforce that were male – however, in other respects the two workforces were quite different. The incidence of full-time employment in the water supply subsector was 95.3%, whereas for recycling the full-time employment rate was 89.7%, these two being either side of the industrial average of 92.7% but both above the non-financial business economy average. In terms of the age profile of the workforce the differences were more substantial, with workers aged less than 30 accounting for 20.2% of the recycling workforce, but just 14.7% of the water supply workforce. In compensation the proportion of older workers (aged 50 or over) was 29.6% for water supply compared with 22.2% for recycling. As such, the water supply subsector had the fourth lowest proportion of younger workers of any non-financial business economy NACE division, and the second highest proportion of older workers.

Expenditure, productivity and profitability

Investment by the EU-27's water supply subsector was EUR 11.4 billion in 2006, dwarfing the EUR 2.1 billion of investment by the recycling subsector, the combined total equivalent to 1.3% of non-financial business economy investment. Nevertheless, relative to their size (in value added terms), both subsectors had high levels of investment: the recycling subsector's [investment rate](#) was 25.9%, above the non-financial business economy average of 18.4%, while that for the water supply subsector was 49.2%, the highest of any industrial NACE division and the fourth highest among all non-financial business economy NACE divisions. Nearly every Member State¹⁵⁵ recorded a higher investment rate for the water supply and recycling sector than for the non-financial business economy as a whole, the exceptions being Bulgaria (2005) and Portugal.

An analysis of [operating expenditure](#) also shows diversity between the two subsectors: [personnel costs](#) accounted for 28.5% of operating expenditure in the EU-27's water supply subsector in 2006, and 9.6% in the recycling subsector, both far from the non-financial business economy average of 16.1%. As a percentage of the total purchases of goods and services, purchases of energy were more than twice as important for the water supply subsector as for the recycling subsector.

¹⁵⁴NACE Divisions 16, 32, 60 and 73, 2005; NACE Divisions 11 and 12, not available.

¹⁵⁵Bulgaria, Poland and Romania, 2005; Ireland, Greece, Cyprus, Malta and the Netherlands, not available.

In other respects the two subsectors were remarkably similar in the EU-27. They had identical average personnel costs in 2006, EUR 27.3 thousand per employee, slightly below the non-financial business economy average of EUR 28.8 thousand per employee. They also both had above average apparent [labour productivity](#) , particularly water supply where value added averaged EUR 62.8 thousand per person employed. As a consequence, both subsectors recorded high [wage-adjusted labour productivity ratios](#) , as value added per person employed was equivalent to 197.6% of average personnel costs in the recycling subsector and 229.8% for water supply.

In terms of operating [profitability](#) , measured here by the [gross operating rate](#) , the EU-27's water supply subsector recorded a rate of 28.1% in 2006, equivalent to 2.6 times as high as the non-financial business economy average rate of 10.8%, and the third highest rate among the industrial NACE divisions. In contrast, the gross operating rate for the recycling subsector was 9.8%, just below the non-financial business economy average.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include [short-term statistics \(STS\)](#) and the [Labour force survey \(LFS\)](#) .

Water supply statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#) . According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers statistics for the public water supply, corresponding to NACE Division 41, which is part of the [water supply and recycling](#) sector. The activities covered in this article are four processes performed on water in the public water supply:

Source: Eurostat (SBS)

Table 4: Collection, purification and distribution of water (NACE Division 41). Main indicators, 2006 (1)

- collection;
- purification;
- desalination;
- distribution.

This article does not cover the collection and treatment of sewage and other waste (NACE Classes 90.01 and 90.02).

It should also be noted that some water, particularly when used in production processes, does not come from the public water supply system, but rather is extracted directly from its source.

Main statistical findings

The volume of public water supply (PWS) is shown, with information on the proportion supplied to households and the extent of their connection to the PWS network in 2006. Although the data set is incomplete, in all available Member States the proportion of households connected to the PWS was close to or in excess of three quarters and in many Member States the proportion exceeded 90%. In most Member States in 2005 the majority of the population was connected to the urban wastewater collecting system and most wastewater was treated after collection.

Structural profile

In 2006, the EU-27's water supply sector (NACE Division 41) was made up of approximately 9.0 thousand enterprises which generated EUR 23.3 billion of value added and employed 370.7 thousand persons. As such, this activity accounted for around three quarters of water supply and recycling (NACE Divisions 41 and 37) value added and a slightly smaller share of employment in the EU-27.

The United Kingdom and Germany had the largest water supply sectors in value added terms, both generating over EUR 5 billion of value added in this sector in 2006, twice as much as the next largest Member State, France. In terms of employment, however, this sector was largest in Poland and Germany, both with workforces in excess of 40.0 thousand persons, followed by Romania and France. In value added terms, the water supply sector was relatively most important in Slovakia and Bulgaria (2005)¹⁵⁶, where it contributed more than 1% to non-financial business economy (NACE Sections C to I and K) value added; Sweden was by far the least specialised in this sector in that its contribution to Swedish non-financial business economy value added was just 0.04% in 2006.

Expenditure and productivity

Investment by the EU-27's water supply sector was valued at EUR 11.4 billion in 2006, equivalent to 49.2% of the sector's value added, making this the highest investment rate of any industrial NACE division and the fourth highest among all non-financial business economy NACE divisions. Exceptionally high investment rates were recorded in Sweden, Lithuania and Belgium, all in excess of 100%.

Personnel costs accounted for 28.5% of operating expenditure in the EU-27's water supply sector in 2006, a share that was well above the non-financial business economy average, and the third highest among the industrial NACE divisions. Despite this high share, average personnel costs in this sector in 2006 were EUR 27.3 thousand per employee, slightly below the non-financial business economy average. In contrast, apparent labour productivity was particularly high, at EUR 62.8 thousand per person employed, resulting in a wage-adjusted labour productivity ratio of 229.8%. Exceptionally high wage-adjusted labour productivity ratios were recorded in the United Kingdom (537.4%) and Finland (373.5%) where this indicator for the water supply sector was at least twice as high as national non-financial business economy averages.

Data sources and availability

The main part of the analysis in this article is derived from structural business statistics (SBS), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include the Eurostat water statistics.

Context

The organisation of water supply within the EU varies between countries, with state-owned, private and mutual enterprises, as well as municipalities involved in terms of the ownership or operation of infrastructure.

Among the key issues that affect this sector are the quality of drinking water, and the efficient use of water resources, the latter concerning issues such as pricing, repair of leakages, metering of water use, and water efficient practices. Furthermore, the cost of related services (such as wastewater collection and treatment) is an important factor, as is the impact of changes in consumption patterns, for example, the increased use of water related to growth in tourism particularly in areas with scarce water resources.

Notes

Water supply, sewerage, waste management and remediation statistics - NACE Rev. 2

Data from April 2012, most recent data: Further Eurostat information, Main tables and Database

This article presents information relating to the European Union's (EU's) water supply, sewerage, waste management and remediation activities, as covered by NACE Rev. 2 Section E.

Water supply refers to the collection, purification, desalination and distribution of water. Sewerage activities concern the operation of sewer systems or sewage treatment facilities that collect, treat, and dispose of sewage. Water supply activities are often carried out in conjunction with, or by units also engaged in, the treatment of sewage.

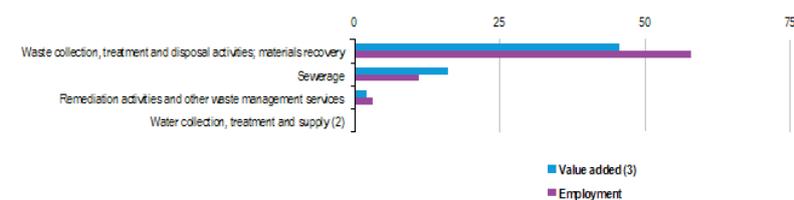

This sector also includes the management of other forms of waste, whether solid or non-solid, industrial or household – including the dismantling of wrecks and the operation of materials recovery facilities. Finally, it also covers remediation activities such as decontamination.

Main statistical findings

Structural profile

There were 58000 thousand [enterprises](#) classified within the EU-27's water supply, sewerage, waste management and remediation activities sector (Section E) in 2009; together they employed 1.3 million persons and generated EUR 78600 million of value added.

Enterprises in this sector were, on average, relatively large, as the water supply, sewerage, waste management and remediation activities sector contributed only 0.3% of the total number of enterprises in the EU-27's [non-financial business economy](#) (Sections B to J and L to N and Division 95), but accounted for 0.9% of its workforce and 1.4% of added value. Compared with the other NACE sections within the non-financial business

economy this sector was the second smallest in terms of value added (larger than mining and quarrying) and the third smallest in terms of its number of enterprises and persons employed (larger than mining and quarrying as well as electricity, gas, steam and air conditioning supply).

Average personnel costs within the EU-27's water supply, sewerage, waste management and remediation activities sector were EUR 31.5 thousand per employee in 2009, slightly above the EUR 30.0 thousand per employee average in the non-financial business economy. **Apparent labour productivity** in the sector was EUR 62 thousand per person employed, almost 50% above the non-financial business economy average (EUR 41.6 thousand per person employed). The **wage-adjusted labour productivity ratio** gives an idea of the extent to which apparent labour productivity relates to average personnel costs. For the EU-27's water supply, sewerage, waste management and remediation activities sector in 2009 this ratio was 196.8% showing that the value of output per person was almost twice as high as the average cost of personnel input; this was well above the non-financial business economy average (138.8%) and was the fourth highest ratio among the NACE sections within the non-financial business economy.

Sectoral analysis

In employment terms, waste and materials recovery (Division 38) was the largest subsector in the EU-27, occupying nearly three fifths (57.9%) of the workforce within the water supply, sewerage, waste management and remediation activities sector in 2009 – see Figure 1. This large share was principally due to the size of the workforce in waste collection (Group 38.1) which alone accounted for one third (32.9%) of the workforce in the water supply, sewerage, waste management and remediation activities sector. Water supply (Division 36), followed by sewerage (Division 37), while remediation activities and other waste management services (Division 39) accounted for a 3.0% share of the sector's workforce. This ranking was repeated in value added terms, although the relative importance of waste and materials recovery was lower (45.5% of sectoral value added).

The activities shown in Table 2b can be split between those where the EU-27 had relatively high apparent labour productivity in 2009 – the water supply and sewerage subsectors – and those that reported apparent labour productivity that was considerably lower (although still above the non-financial business economy average of EUR 41.6 thousand per person employed), namely, the waste collection and remediation activities and other waste management services subsectors. In contrast, there was far less variability in terms of the average personnel costs that were recorded for the EU-27 by each subsector in 2009; each activity reported average personnel costs that were slightly above the non-financial business economy average of EUR 30 thousand per employee, ranging from a high of EUR 33.7 thousand per employee for sewerage down to EUR 30.5 per employee for waste collection. As a result of the relatively narrow range of average personnel costs per employee, the ranking of activities according to their wage-adjusted labour productivity ratios broadly reflected their respective levels of apparent labour productivity. The highest ratio was recorded for the sewerage subsector (269.0%), while the ratio for waste collection (159.2%) was considerably lower than the sectoral average (196.8%), although stood above the non-financial business economy average of 138.8%.

Country analysis

As for electricity, gas, steam and air conditioning supply, the water supply, sewerage, waste management and remediation activities sector contributed a relatively large share of the non-financial business economy workforce in a number of Member States in central and eastern Europe. The water supply, sewerage, waste management and remediation activities sector provided employment to 1.5% or more of the non-financial business economy workforce in 2009 in Slovakia, Romania, Hungary, Bulgaria, the Czech Republic, Lithuania and Slovenia; in Cyprus, Luxembourg and Ireland this sector contributed 0.5% of the non-financial business economy workforce. The water supply, sewerage, waste management and remediation activities sector accounted for a greater share of non-financial business economy value added than employment in the majority of the Member States in 2009, with the only exception being Romania, while the respective shares were equal in the Czech Republic, Denmark (data are for 2008), Ireland and France (where the employment share is based on the number of employees). The relative importance of value added was much higher in Cyprus and the United Kingdom, as the share of value added in the national non-financial business economy total was more than twice that recorded for employment, indicating particularly high apparent labour productivity relative to national non-financial business economy averages.

Table 3 shows that there are a number of country-specific cases of specialisation within the water supply, sewerage, waste management and remediation activities sector. Among the Member States, Spain accounted for close to half (46.3%) of the EU-27's value added in remediation activities and other waste management services in 2009, while the United Kingdom had the highest value added in the water supply and sewerage sectors, and Italy the highest level of value added for waste collection.

In absolute terms, Germany and Italy had the largest workforces in the water supply, sewerage, waste management and remediation activities sector, each with more than 175 thousand persons employed (note that the employment data available for France is based on the number of employees). In terms of value added, the United Kingdom had by far the largest water supply, sewerage, waste management and remediation activities sector, generating EUR 16300 million in 2009, almost twice the level recorded in France and Italy (note there is no value added data available for Germany). These very different levels are reflected in the apparent labour productivity figures with the United Kingdom averaging value added of EUR 118.9 thousand per person employed, far ahead of the second highest value, EUR 102.3 thousand per person employed in Belgium and also twice the EU-27 average (EUR 62.0 thousand per person employed). Despite average personnel costs somewhat above the EU-27 average, the United Kingdom still recorded the highest wage-adjusted labour productivity ratio in the water supply, sewerage, waste management and remediation activities sector (335.5%), followed by Cyprus (288.1%).

Data sources and availability

Coverage

This article presents an overview of statistics for the EU's water supply, sewerage, waste management and remediation activities sector, as covered by NACE Rev. 2 Section E. This NACE section is composed of four NACE divisions, namely:

- water supply (Division 36) which concerns the collection, purification, desalinisation and distribution of water. Some water, particularly when used in production processes, does not come from the [public water supply](#) system, but rather is extracted directly from its source. The (typically long distance) transport of water via pipelines is excluded.
- sewerage activities (Division 37) which concern the operation of sewer systems or sewage treatment facilities that collect, treat, and dispose of sewage. Activities of water supply are often carried out in connection with, or by units also engaged in, the treatment of sewage.
- the management (including collection, treatment and disposal) of other forms of waste (Division 38), whether solid or non-solid waste, industrial or household waste, including the dismantling of wrecks and the operation of materials recovery facilities. Materials recovery includes the processing of metal and non-metal waste and scrap and other articles into secondary raw materials: the processing may involve a number of stages such as separating, sorting, crushing, shredding, cutting, melting, grinding, pressing, stripping, cleaning and composting. The output of the waste or sewage treatment process can either be disposed of or become an input into other production processes. Materials recovery does not extend to the production of new final products, nor does it include wholesaling of recoverable materials. Materials recovery does not cover reprocessing of nuclear fuels. Note also that substantial materials recovery may be carried out by enterprises as ancillary activities, without the involvement of enterprises in the waste management subsector.
- remediation activities (Division 39) such as decontamination.

Data sources

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

The organisation of water supply within the EU varies between Member States, with state-owned, private and mutual enterprises, as well as municipalities involved in terms of the ownership or operation of infrastructure. Among the key issues that affect this sector are the quality of drinking water, and the efficient use of water resources, the latter concerning issues such as pricing, repair of leakages, metering of water use, and water-efficient practices. Furthermore, the cost of related services (such as [wastewater](#) collection and treatment) is an important factor, as is the impact of changes in consumption patterns, for example, the increased use of water related to growth in tourism particularly in areas with scarce water resources.

Adopted in 2000, the [Water framework Directive](#) provides the basis for water policy within the EU. This framework directive is built on four main pillars:

- coordinated action to achieve 'good status' for all EU waters, including surface and groundwater, by 2015;
- setting up a water-management system based on natural river basin districts, crossing regional and national boundaries – at the time of writing most but not all [river basin management plans](#) had been adopted;
- integrated water management, bringing different water management issues into one framework;
- active involvement of interested parties and consultation of the public.

In 2006 and early 2007 the [European Commission](#) carried out an assessment of water scarcity and droughts in the EU. Based on this, in July 2007 it proposed an initial set of policy options to increase water efficiency and water savings in the form of a Communication [addressing the challenge of water scarcity and droughts in the European Union](#) . Seven policy options were identified for tackling water scarcity and drought issues:

- putting the right price tag on water;
- allocating water and water-related funding more efficiently;
- improving drought risk management;
- considering additional water supply infrastructures;
- fostering water efficient technologies and practices;
- fostering the emergence of a water-saving culture;
- improving knowledge and data collection.

In 2012 the European Commission asked the public for its views on the most appropriate actions to improve water management in Europe. These views will help to formulate the policy proposals to be included in a blueprint to safeguard Europe's water resources which is planned for the end of 2012.

The EU's [sixth environment action programme \(EAP\)](#) runs from 2002 to 2012 and identifies waste prevention and management as one of four top priorities. Its primary objective is to decouple waste generation from economic activity. Work on defining the seventh environmental action programme is underway, with initial research suggesting that the final programme could address aspects such as:

- rapidly changing external conditions and the increasingly interlinked nature of environmental, economic and social challenges;
- increased growth in the demand for natural resources and the impact of this on the environment;
- biodiversity loss (terrestrial and marine), waste generation and air quality in urban areas;
- changing the behaviour of consumers to ease pressures on the environment;
- exploring the role of urban communities and urban policy to deliver environmental improvements;
- a renewed emphasis on the international aspect of environmental policy, setting the basis for global green growth and striving for better global environmental governance.

In November 2008 a [Waste framework Directive](#) was adopted which introduces a binding five-step waste hierarchy where prevention is the preferred option followed by re-use, [recycling](#) and other forms of recovery, with disposal such as [landfill](#) used only as a last resort. Unless properly regulated, the disposal of waste may have a serious environmental impact: landfills, for example, can take up land space and may cause air, water and soil pollution, while [incineration](#) can result in emissions of dangerous air pollutants.

EU policy aims to move waste management up the waste hierarchy taking into account environmental impacts over the entire life cycle. Waste prevention can be achieved through cleaner technologies, better design, or more efficient production and consumption patterns; as well as reducing waste these preventative actions may lead to reductions in resource consumption throughout production and distribution chains.

EU legislation sets binding targets for Member States on the recovery and recycling/re-use of municipal waste, batteries, electrical and electronic waste, construction and demolition waste, end-of-life vehicles and packaging.

Table 4b: Key indicators, water transport (NACE Division50), 2009 - Source: Eurostat (sbs_na_1a_se_r2)

Main statistical findings

Structural profile

There were just over 17 thousand enterprises operating with water transport services (Division50) as their main activity in the EU-27 in 2009. Together they employed 220.9 thousand persons, which was equivalent to 0.2% of the overall non-financial business economy (Sections B to J and L to N and Division95) workforce, or 2.1% of those employed in transportation and storage (Section H). Water transport services enterprises generated EUR21844 million of value added which was 0.4% of the non-financial business economy total and 5.0% of the transportation and storage total.

The apparent labour productivity of the EU-27's water transport services sector in 2009 was relatively high at EUR99 thousand per person employed. Indeed, this marked the tenth highest level of apparent labour productivity among all of the NACE divisions covered by the non-financial business economy and was more than double the non-financial business economy average of EUR41.6 thousand per person employed or the transportation and storage average of EUR41 thousand per person employed. Water transport services had the highest level of apparent labour productivity among any of the five NACE divisions that make-up transportation and storage services.

Average personnel costs within the EU-27's water transport services sector were also relatively high at EUR49.2 thousand per employee in 2009 compared with EUR30.0 thousand per employee for the whole of the non-financial business economy and an average of EUR31.2 thousand per employee across transportation and storage services, where the only NACE division to record higher average personnel costs was that of air transport .

The wage-adjusted labour productivity ratio , which combines the two previous indicators and shows the extent to which value added per person employed covers average personnel costs per employee, stood at 201.1% for the EU-27's water transport services sector in 2009. This was also considerably above both the non-financial business economy average of 138.8% and the transportation and storage average of 132.1% and marked the highest level for this ratio among any of the five NACE divisions within transportation and storage services.

The gross operating rate (which presents the relation between the gross operating surplus and turnover) is one measure of profitability; it stood at 12.6% for the EU-27's water transport services sector in 2009, which was almost the same as the average for the whole of transportation and storage (12.2%), while being somewhat higher than the non-financial business economy average (9.7%).

Sectoral analysis

The four different NACE groups that compose the water transport services sector each comprised between 3.0 and 5.5 thousand enterprises across the EU-27 in 2009. The highest number of enterprises was recorded for the inland freight water transport subsector (Group50.4), which was equivalent to almost one third (32.5%) of the water transport services total.

The pattern was quite different for the breakdown of employment as more than four out of five persons in the EU-27's water transport services sector in 2009 worked in one or other of the two sea and coastal water transport services subsectors. The largest workforce (101.6 thousand persons) was registered for sea and coastal freight water transport (Group50.2), while the sea and coastal passenger water transport subsector (Group50.1) accounted for a further 78.1 thousand persons. The two inland water transport services subsectors had quite similar sized workforces, as 22.6 thousand persons were employed within the freight subsector, while the smallest workforce (18.5 thousand) was registered amongst those persons engaged in inland passenger water transport services (Group50.3).

The relative importance of the EU-27's sea and coastal freight water transport subsector was far higher in terms of value added, reaching EUR17759 million in 2008, which was approximately four fifths of the water transport services total (note that in Figure 1 and Table 2a there are mixed reference periods for value added across the four NACE groups). The high share of value added for sea and coastal freight water transport was reflected in its apparent labour productivity which stood at EUR181 thousand per person employed in 2008; this was the ninth highest value across all of the NACE groups within the non-financial business economy.

EU-27 apparent labour productivity in 2009 was also relatively high for the inland freight water transport subsector (EUR84 thousand per person employed) and for the sea and coastal passenger water transport subsector (EUR71 thousand per person employed); these two subsectors also recorded wage-adjusted labour productivity ratios (234.5% and 158.6% respectively) that were above the non-financial business economy average (138.8%). The gross operating rate for inland freight water transport (28.2%) was almost three times as high as the non-financial business economy average (9.7%) and was the thirteenth highest ratio among the NACE groups that compose the non-financial business economy. In contrast, the inland passenger water transport subsector recorded apparent labour productivity that was, at EUR35 thousand per person employed in 2008, below the non-financial business economy average.

Country analysis

Germany had the largest water transport services sector in the EU-27 in terms of both its share of the workforce and its share of value added. Some 16.7% of those employed in this sector within the EU-27 in 2009 were working in Germany, followed by 14.4% in Italy and 11.5% in the Netherlands (note that there is no information available for France); none of the remaining Member States accounted for more than the 7.9% employment share recorded for Sweden.

In value added terms the relative importance of German activity was considerably higher, accounting for more than one third (36.5%) of the EU-27's added value in 2009; there were also double-digit shares for Denmark (2008), Italy, the Netherlands and the United Kingdom. Germany had the highest share of EU-27 value added in 2009 for three out of the four NACE groups within the water transport services sector, with the sea and coastal passenger water transport subsector the only exception – where Italy accounted for around one third of the EU-27's added value.

In terms of relative specialisation, as measured by the national shares of water transport services in non-financial business economy value added, Denmark (2008) was the most specialised Member State. Water transport services accounted for 2.5% of non-financial business economy added value in Denmark in 2008, which was almost 6.5 times as high as the average across the EU-27 in 2009. The highest degree of specialisation for sea and coastal passenger water transport services in 2009 was recorded in Cyprus, while for sea and coastal freight water transport services the most specialised Member State was Lithuania. For the inland water transport subsectors the highest degrees of specialisation were recorded in Portugal for passenger transport and in Romania for freight.

In keeping with the overall figures for the EU-27, most of the Member States reported relatively high levels of apparent labour productivity and average personnel costs within the water transport services sector in 2009. This was particularly true in Germany, Ireland, Italy, the Netherlands and the United Kingdom in 2009,

as well as in Belgium and Denmark in 2008.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the water transport services sector in the EU, as covered by NACE Rev.2 Division50. This division includes all water borne transport services whether these are scheduled or not; it excludes own account transport. Also included are the operation of towing or pushing boats (as well as barges and rigs), excursion, cruise or sightseeing boats, ferries, water taxis and so on, as well as the rental of pleasure boats with crew for water transport (for example, for fishing cruises).

A distinction is made between transport on inland waterways as opposed to sea and coastal water transport — the deciding factor is in fact the type of vessel used. A further distinction is made between the transport of passengers and freight, such that four separate NACE groups cover the whole of this services sector, which includes:

- sea and coastal passenger water transport (Group50.1);
- sea and coastal freight water transport (Group50.2);
- inland passenger water transport (Group50.3);
- inland freight water transport (Group50.4).

The renting of pleasure boats, yachts and commercial ships or boats without crew is excluded (part of Division77, covering the [renting and leasing of goods](#)) as are harbour and port operations and other auxiliary activities such as docking, pilotage, lightering, vessel salvage (part of Division52, covering [warehousing and support activities for transportation](#)).

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), the present article covers water transport statistics, corresponding to NACE Division 61, which is part of the [transport and storage](#) sector. This article covers all water transport activities, both:

- sea and coastal transport or maritime transport(NACE Group 61.1);
- inland water transport (NACE Group 61.2).

For information on water transport networks and [ports](#), see [Warehousing and transport logistics statistics - NACE Rev. 1.1](#).

Table 5: Water transport (NACE Division 61). Main indicators, 2006 (1)

Main statistical findings

Structural profile

Employment in the EU-27's water transport sector (NACE Division 61) sector in 2005 was 213.5 thousand persons. In 2006, there were 18.9 thousand enterprises in this sector, with combined turnover valued at EUR 100 billion resulting in value added of EUR 22.0 billion. As such, this sector contributed around 5.5% of the wealth created in all transport services (NACE Divisions 60 to 63) in 2006 but a much smaller proportion (2.4%) of the transport services workforce in 2005. Sea and coastal transport (NACE Group 61.1) dominated the water transport sector, with EUR 20.0 billion of value added in 2006 and 171.9 thousand persons employed in 2005, the remainder accounted for by inland water transport (NACE Group 61.2).

The relative importance of water transport depends largely on geographical, climatic, or historical factors. Close to one quarter of added value generated in the transport services sector was accounted for by water transport in Cyprus (23.1%, 2005), while this share was close to one fifth in Denmark (19.2%) and Greece (19.1%). In contrast, all of the Member States with no coastline reported only limited activity within the water transport sector, which accounted for no more than 1% of the total value added created within the transport services sector. For the third consecutive year Estonia recorded the unusual situation of a negative value added for water transport in 2006, indicating that the intermediate consumption (purchases of goods and services adjusted for changes in stocks) exceeded production value.

The high level of specialisation in the water transport sector in some of the smaller and medium-sized Member States resulted in them contributing particularly large shares of total EU-27 value added and employment in this sector. The Netherlands and Denmark were the fourth and fifth largest Member States in value added terms, while the Greek water transport sector's workforce represented 9.0% of the EU-27 total. Denmark and Greece emerged as the second and third most specialised Member States¹⁵⁷ in water transport (based on their value added), behind Cyprus (2005). An analysis of the two subsectors shows particular specialisations in some Member States. For example, in the Netherlands inland water transport was much more significant, accounting for more than one third (37.2%) of Dutch water transport value added; this was reflected in the fact that the Netherlands had the largest inland water transport subsector in the EU-27

, approximately two fifths of EU-27 value added.

Among the transport services NACE divisions, the EU-27's water transport sector recorded the strongest growth in turnover between 2000 and 2007, an average increase of 7.2% per year over this period, nearly two percentage

¹⁵⁷Bulgaria, Cyprus and Poland, 2005; the Czech Republic, Ireland, Malta, the Netherlands and Romania, not available.

points more than the [non-financial services](#) average (NACE Sections G to I and Divisions 72 and 74). In contrast, the employment index for water transport recorded an average fall of 2.2% per year over the period 1998 to 2007, the only transport services NACE division to record an overall reduction in employment during this period. This was due to a strong fall in employment between 1999 and 2002; after which the water transport employment index only fell in one year (-0.6% in 2006), and averaged growth of 1.1% per year in the period 2002 to 2007.

Transport of goods and passengers

A majority of the merchant fleet controlled from the EU-27 sails under foreign flags – this proportion is roughly two thirds whether calculated based on the number of ships or their tonnage.

Sea transport, for the total movement of goods, combining inward and outward transport, reached 3800 million tonnes in the EU-27 in 2007. The United Kingdom accounted for the largest share of sea transport of goods (both inward and outward), with 15.2% of the EU-27 total, followed by Italy (13.6%), the Netherlands (13.2%) and Spain (11.1%). Only in the [Baltic Member States](#) and Poland did the outward volume of sea freight transport exceed the inward volume, with Malta having by far the highest ratio of inward to outward sea freight transport.

The total number of sea passengers in the EU-27 was 397.6 million in 2007 (inward plus outward), of which Greece (23.2%) and Italy (21.6%) provided by far the largest shares. The Nordic trio of Denmark (12.2%), Sweden (8.2%) and Finland (4.1%) also contributed relatively high shares, as did Malta (2.0%). In contrast to goods transport, the inward and outward flows of passengers are similar in nearly all Member States with the exception of Sweden where there were half a million more inward transported passengers as outward.

Expenditure and productivity

The EU-27's water transport sector recorded a particularly high [investment rate](#), with gross [tangible investment](#) equivalent to 45.5% of value added in 2006, approximately two and a half times as high as the [non-financial business economy](#) average (18.4%). Denmark recorded the largest level of gross tangible investment in the water transport sector in 2006, with investment valued at EUR 2.4 billion, while investment also exceeded EUR 1.3 billion in France, Italy and the Netherlands.

The share of [personnel costs](#) in total operating expenditure was as high as 20.0% in the EU-27's inland water transport subsector in 2006, compared with just 8.0% in the sea and coastal transport subsector, around one third the transport services average (22.5%).

Water transport services were characterised by high apparent [labour productivity](#) with an average EUR 120.0 thousand of value added per person employed in the EU-27 in 2005. The sea and coastal transport subsector recorded a value of EUR 135.3 thousand per person employed, while the inland water transport average of EUR 50.0 thousand per person employed was much closer to the transport services average. Average personnel costs were also above the transport services average, but not to the same extent as for apparent labour productivity, resulting in high [wage-adjusted labour productivity ratios](#); for the sector as a whole a ratio of 280.0% was recorded in 2005 in the EU-27, with the sea and coastal transport subsector recording a ratio of 300.1% and the inland water transport subsector a ratio of 175.0%, both well above the transport services average (141.9%) in the same year. Due to its negative value added Estonia recorded a negative wage-adjusted labour productivity ratio in the water transport sector in 2006, while Austria and Hungary both recorded ratios below 100% as a result of average personnel costs exceeding apparent labour productivity.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include [short-term statistics \(STS\)](#) , [Eurostat](#) maritime transport statistics and ISL merchant fleet databases, based on the Lloyd's Maritime Information System, in EU energy and transport in figures statistical pocketbook 2007/2008, European Commission, Directorate-General for Energy and Transport.

Context

The transport and storage sector focuses on transport services provided to clients for hire and reward. When analysing transport traffic volumes (for example, tonnes of freight) as presented in this article, it is important to bear in mind that these include own account transport as well as transport services for hire and reward. This is particularly important in road transport where, for example, a manufacturer might collect materials or deliver own [output](#) , rather than contracting a transport service enterprise to do this. Equally, the use of own vehicles (typically [passenger cars](#)) accounts for a very large part of passenger transport. Such own account transport does not contribute towards the statistics on the transport services sector.

EU transport policy is based upon the 2001 White paper ' [European transport policy for 2010: time to decide](#) ' and the 2006 mid-term review in the European Commission's communication ([COM\(2006\) 314](#)) 'Keep Europe moving – sustainable mobility for our continent'. In 2007 the European Commission adopted a communication ([COM\(2007\) 606](#)) on 'Keeping freight moving', to make rail freight more competitive, facilitate modernisation of ports, and review progress in the development of sea shipping.

Environmental issues remain of great importance to this sector, as transport is a major source of emissions and noise. In 2008 the European Commission put forward a package of measures related to road and rail transport referred to as 'Greening Transport'. This included a communication ([COM\(2008\) 433](#)) summarising the packages and initiatives planned for 2009, a strategy to internalise the cost of transport externalities, a proposal for a Directive on road tolls for lorries, and a communication on rail noise. The overall thrust of the package is to try to move towards more sustainable transport.

Maritime freight shipping is made up of line (generally scheduled services) and tramp shipping, with a distinction between tankers (liquid and gas) and bulk carriers, and between containerised and general cargo. The EU relies heavily on maritime transport for its external trade. As well as freight, maritime transport activities also cover passenger transport, for example, scheduled ferry services and cruises. Inland navigation traditionally holds a strong market share in the transport of bulk cargo (such as iron ores, construction materials and metal products).

Notes

Wholesale trade statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

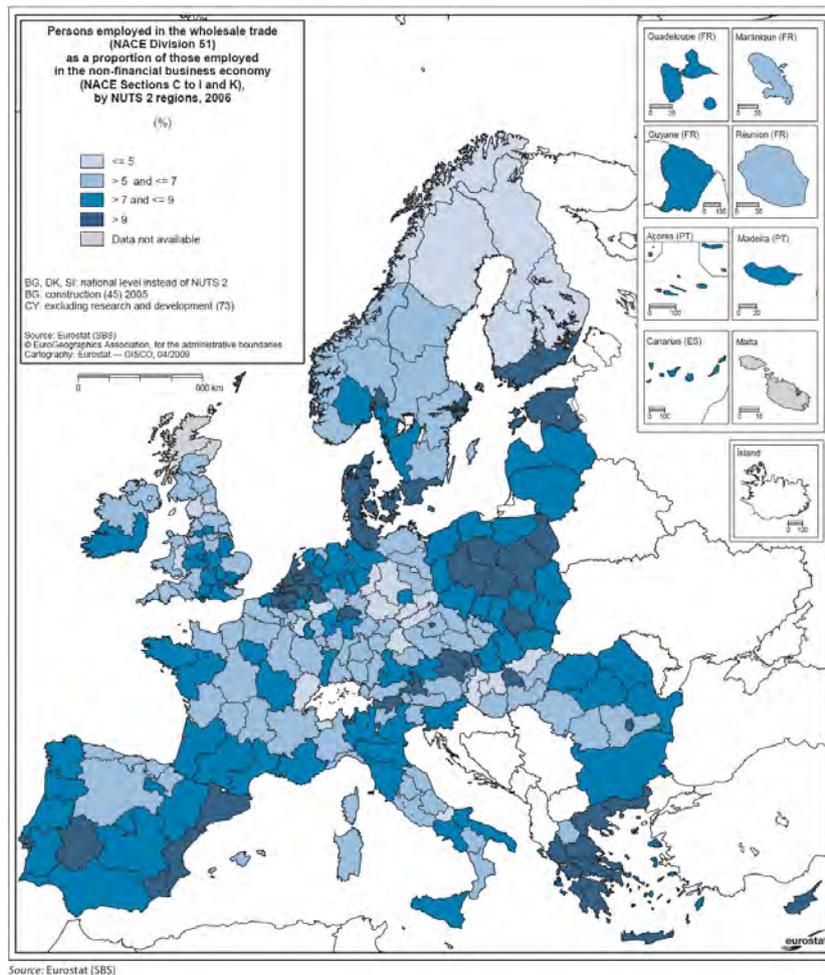

This article introduces a [set of statistical articles](#) which analyse the structure, development and characteristics of the economic activities in the [wholesale trade](#) sector in the [European Union \(EU\)](#) . According to the statistical classification of economic activities in the EU ([NACE Rev 1.1](#)), this sector covers NACE Division 51, and its activities are treated in more depth in six further articles covering:

- [Fee and contract wholesale trade](#) , corresponding to NACE Group 51.1;
- [Agricultural wholesale trade](#) , corresponding to NACE Group 51.2;
- [Consumer goods wholesale trade](#) , corresponding to NACE Groups 51.3 and 51.4;
- [Intermediate goods wholesale trade](#) , corresponding to NACE Group 51.5;
- [Machinery and equipment wholesale trade](#) , corresponding to NACE Group 51.8;
- [Non-specialised wholesale trade](#) , corresponding to NACE Group 51.9.

Table 5: Wholesale and commission trade (NACE Division 51). Main indicators, 2006 (1)

Main statistical findings

Structural profile

By most output measures the EU-27's wholesale trade sector (NACE Division 51) was one of the largest sectors within the EU-27's non-financial business economy (NACE Sections C to I and K). It comprised 1.7 million enterprises in 2006, that together generated EUR 4603 billion of turnover and EUR 518.8 billion of value added. As such, this was by far the largest of all the structural business statistics sectors in terms of turnover, recording 20.6% of all turnover generated within the non-financial business economy, more than double the share of retail trade and repair (see [Retail trade and repair statistics - NACE Rev. 1.1](#)). This very high share of turnover reflects the nature of wholesaling, buying and reselling goods often in very large quantities – box 1 below focuses on own-account wholesale turnover. Wholesale trade's 9.2% share of value added was the second highest among the structural business statistics sectors, lower only than the 15.8% share of business services (see [Business services statistics - NACE Rev. 1.1](#)). The wholesale trade sector was less influential in terms of employment, as the 10.0 million persons employed in this sector registered a 7.7% share of the EU-27's non-financial business economy workforce in 2006; the high value added and lower employment shares indicate an above-average level of apparent labour productivity.

Among the activities that compose the wholesale trade sector, own-account wholesale trade (NACE Groups 51.2 to 51.9) accounted for 92.4% of the EU-27's wholesale trade value added in 2006, while wholesale on a fee or contract basis (NACE Group 51.1) accounted for the remainder. Wholesale on a fee or contract basis was particularly important in Slovenia, Italy and Slovakia, where its contribution to wholesale trade value added was more than double the EU-27 average. The largest own-account wholesale trade subsector in value added and employment terms was the wholesale trade of consumer goods (NACE Groups 51.3 and 51.4) – followed by the wholesale of non-agricultural intermediate products, waste and scrap (NACE Group 51.5) and machinery, equipment and supplies (NACE Group 51.8), both of which made a larger contribution to sectoral value added than employment.

The United Kingdom and Germany had the largest¹⁵⁸ levels of value added, turnover and employment in the wholesale trade sector. Relative to the whole non-financial business economy, the importance of the wholesale trade sector varied from just 7.4% of the value added in Finland to 15.4% in Latvia and 16.0% in Greece, with both Germany (7.6%) and the United Kingdom (8.5%) relatively unspecialised. For more than half of the Member States the wholesale trade sector was the largest or second largest structural business statistics sector in the non-financial business economy in value added terms; it was the largest sector in Estonia, Greece, Latvia, Poland and Romania.

¹⁵⁸Bulgaria and Poland, 2005; Malta, not available.

Regional employment specialisation (in some cases the whole country is treated as one region) can be seen from the map which is based on the non-financial business economy employment share of the wholesale trade sector. Given the essential nature of many parts of wholesale trade, providing services directly to retailers and to industrial consumers, it is unsurprising that most regions tended towards the average. In the regions where the wholesale trade workforce accounted for its highest share of the [non-financial business economy](#) workforce (around 15% in two Greek regions), the relative specialisation was around five times higher than in the least specialised regions (as wholesale activities accounted for around 3% of the workforce in two Finnish regions): only in retail trade and repair was there a lower ratio between the most and least specialised regions.

Employment for the EU-27's wholesale trade sector increased in 2007, up 2.9%, the fourth consecutive year of an increase in the rate of employment growth. Over the period 1997-2007, the [index of employment](#) recorded one slight negative year on year rate of change, -0.5% in 2003, and averaged growth of 1.1% per year during this ten year period. The [index of turnover](#) grew by 7.6% in 2007, slower than the 9.0% growth recorded in 2006, and the first slowdown in the rate of growth in five years. During the period 1997-2007, the index of turnover rose on average by 4.9% per year.

Turnover indices for the largest subsectors show that during each of the last five years the strongest growth was recorded by the wholesaling of non-agricultural intermediate goods, waste and scrap. In 2007 this subsector recorded growth of 7.7%, considerably less than the 13.8% recorded in 2006 and the 17.0% recorded in 2005. Over the period 2000 to 2007 this subsector grew on average by 7.3% per year, the highest average annual growth rate over this period of all available non-financial services¹⁵⁹. However, note that this activity covers the wholesaling of fuels, and such products recorded large price increases towards the end of the period studied and these are also reflected in the turnover index.

The two consumer oriented NACE groups, namely the wholesale of food, beverages and tobacco, and of household goods, recorded uninterrupted year on year sales growth between 2000 and 2007, resulting in average annual growth rates of 3.9% and 4.4% per year respectively.

The turnover index for the wholesaling of machinery, equipment and supplies showed a less regular development, with a decline in output recorded in 2001, 2002 and 2003, since when output increased each year. Looking across these two periods with very different developments this activity's turnover grew on average by 3.0% per year. The two remaining own-account subsectors averaged 3.1% annual growth in the case of agricultural wholesaling and 4.5% annual growth in the case of other wholesaling.

Wholesale trade enterprises averaged EUR 2.7 million of turnover each in 2007, the second highest average sales figures among the activities covered by the non-financial services structural business statistics sectors, slightly smaller than the average recorded for media and communications enterprises. A more detailed analysis of the size of enterprises, for four enterprise size classes shows that in terms of value added, the size class structure of the wholesale trade sector was very evenly distributed, with none of the size classes dominating. As a result, [SMEs](#) (enterprises with less than 250 persons employed) contributed just over three quarters (77.2%) of the value added in the EU-27's wholesale trade sector in 2006, well above the non-financial business economy average of 57.9%. In particular [small enterprises](#) (enterprises with between 10 and 49 persons employed) contributed a particularly high proportion of the wholesale trade sector's value added. In terms of employment, the contribution of the four size classes was less even, with close to one third of the wholesale trade sector's workforce employed in [micro enterprises](#) (with less than 10 persons employed).

Turnover from own-account wholesale trade in the EU¹⁶⁰ Own-account wholesale trade generated EUR 4382 billion of turnover in the EU in 2006. The wholesaling of consumer goods was the largest activity and accounted for 39.7% of own-account wholesale turnover in the EU, a share that exceeded 50% in Romania, Greece, Portugal and Italy. The wholesale of non-agricultural intermediate products, waste and scrap was the second largest of the wholesale trade subsectors, averaging 35.3% of own-account wholesale trade turnover in the EU, but exceeding 50% only in Estonia. The importance of the wholesale of machinery, equipment and supplies varied greatly between Member States, from less than 9% in Poland (2005), Romania, Bulgaria (2005), Cyprus and Slovenia, to over 25% in Ireland and the Netherlands. The wholesale of agricultural raw materials and live animals (NACE Group 51.2) reached its peak share in France (8.7%), double the EU average (4.3%),

¹⁵⁹Note that the services turnover indices are available at a mixture of NACE levels, sometimes, classes, groups, divisions, or special aggregates thereof.

¹⁶⁰Bulgaria and Poland, 2005; Malta, not available

and was less than 7% in all of the Member States except for Hungary. Other wholesale trade (NACE Group 51.9) accounted for 4.8% of own-account wholesale turnover in the EU, but its share exceeded 20% in Slovenia and Slovakia and 30% in Poland (2005).

Employment characteristics

According to [Labour Force Survey](#) data for 2007, two thirds (66.6%) of the EU-27's workforce in wholesale trade were men. This share was only slightly higher than that recorded for the non-financial business economy as a whole, while it was well above the distributive trades' average (51.2%). Slightly less than nine tenths (89.1%) of the persons employed in the EU-27's wholesale trade sector in 2007 worked full-time, a proportion that was 10.8 percentage points above the distributive trades average and slightly above the non-financial business economy average (85.7%) as well. Among the Member States, only in Romania was the incidence of full-time work significantly lower in wholesale trade (90.8%) than in the non-financial business economy as a whole (97.8%), while in Slovenia, Bulgaria and Malta it was slightly lower.

A breakdown by age of the workforce for the EU-27's wholesale trade sector in 2007 shows a lower proportion of younger workers (aged less than 30) when compared with the non-financial business economy average, and a higher proportion of the other two age groups. This was in stark contrast to the situation in the two other distributive trades sectors (motor trades, and retail trade and repair) which recorded particularly high shares of younger workers.

Expenditure, productivity and profitability

The level of [tangible investment](#) made by the wholesale trade sector in 2006 reached EUR 53.1 billion. This was equivalent to 5.1% of the tangible investment made in the whole of the non-financial business economy, a much lower share than the wholesale trade sector recorded in terms of employment or value added. This relatively low level of investment was confirmed by a low investment rate. Investment by the wholesale trade sector was equivalent to 10.2% of the sector's value added, just over half the 18.4% rate recorded for the non-financial business economy as a whole. This was in large part due to an [investment rate](#) of just 7.8% in the wholesale of machinery and equipment subsector, and to the 9.8% rate for the largest subsector, wholesaling of consumer goods. The closest any of the subsectors got to the average rate for the non-financial business economy was 17.6% recorded for agricultural wholesaling.

Purchases of goods and services represented a high share (93.5%) of [operating expenditure](#) in the EU-27's wholesale trade sector, the largest share recorded in 2006 among all the structural business statistics sectors, and the second largest among all of the non-financial business economy NACE divisions, just below the share for the extraction of crude petroleum and natural gas. The high share relating to purchases of goods and services underlines the characteristics of wholesale trade, namely, that it involves the purchase of goods for resale. Consequently the share of [personnel costs](#) (6.5%) was low, particularly so among the subsectors of agricultural wholesaling (4.4%) and the wholesale of non-agricultural intermediate products (4.2%).

Apparent labour productivity was EUR 52.1 thousand per person employed in the EU-27's wholesale trade sector in 2006, EUR 8.5 thousand higher than the non-financial business economy average. However, this ratio varied greatly between the wholesale trade subsectors, ranging from EUR 40.0 thousand per person employed for other wholesale to EUR 64.6 thousand for the wholesale of machinery and equipment. Average personnel costs in the wholesale trade sector were also higher than the non-financial business economy average in 2006, with the same subsectors recording the highest and lowest values.

The [wage-adjusted labour productivity ratio](#) combines the ratios of apparent labour productivity and average personnel costs. This ratio was 159.8% for the EU-27's wholesale trade sector in 2006, marginally above the 151.1% average for the non-financial business economy, and higher than in both of the other distributive trades sectors. Despite having the lowest apparent labour productivity, the particularly low average personnel costs in the other wholesale trade subsector resulted in this subsector having the highest wage adjusted productivity ratio of all of the wholesale trade subsectors, while the lowest ratio was recorded for wholesale trade on a fee or contract basis.

The ratio of the gross operating surplus to turnover (the gross operating rate) was 5.2% in the EU-27's wholesale

trade sector in 2006, less than half the corresponding rate for the non-financial business economy as a whole (10.8%), reflecting the high turnover (resale in the same condition as purchased) and relatively low margins typically associated with wholesale trade activities. The only wholesale subsector to report a gross operating rate above the non-financial business economy average was wholesale on a fee or contract basis (11.0%) which is a not typical wholesaling activity in that it does not involve buying and reselling in large quantities.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#) , including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include [short-term statistics \(STS\)](#) and the Labour force survey (LFS).

Context

The activities in NACE Division 51 cover all wholesale trade except that concerning motor vehicles and motor-cycles (see [Fuel retail and service station statistics - NACE Rev. 1.1](#)): the wholesaling of automotive fuel is considered as a wholesale trade rather than a motor trade. This article covers resale (sale without transformation) of new and used products, as well as wholesale activities carried out on a fee or contract basis.

The wholesaling activity consists of selling to retailers or to industrial, commercial, institutional and professional users. Wholesalers can act on a fee or contract basis as agents (as covered by [Fee and contract wholesale trade statistics - NACE Rev. 1.1](#)) or for their own-account, buying and selling goods. The own-account wholesale sub-sectors distinguish the types of product in which the wholesaler is specialised: agricultural products, consumer goods, intermediate goods, machinery and equipment (covered by [Agricultural wholesale trade statistics - NACE Rev. 1.1](#) , [Consumer goods wholesale trade statistics - NACE Rev. 1.1](#) , [Intermediate goods wholesale trade statistics - NACE Rev. 1.1](#) and [Machinery and equipment wholesale trade statistics - NACE Rev. 1.1](#)), while specialised wholesalers of other products, along with non-specialised wholesalers, are included in [Non-specialised wholesale trade statistics - NACE Rev. 1.1](#) .

In the supply chain, wholesalers are located between producers and users, providing know-how and knowledge in markets for which they have expertise. Competition within the wholesale trade activity is often centred on providing more efficient services or more sophisticated value added services. Wholesalers can provide a range of services from basic storage and break of bulk, sorting, grading and logistics to pre- and post-production operations (for instance, labelling, packaging, bottling and installation).

Notes

Wholesale trade statistics - NACE Rev. 2

Data from April 2012. Most recent data: Further Eurostat information, Main tables and Database .

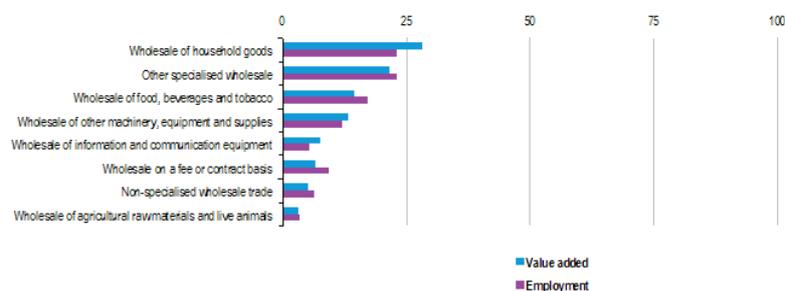

This article presents an overview of statistics for the wholesale trade sector in the [European Union \(EU\)](#) , as covered by [NACE Rev.2 Division46](#). In the supply chain, wholesalers are located between producers and users, providing know-how and knowledge in markets for which they have expertise. Wholesalers can provide a range of services from basic storage and break of bulk, sorting, grading and logistics to pre- and post-production operations (for instance, labelling, packaging, bottling and installation).

Main statistical findings

Structural profile

By most measures the wholesale trade sector (Division46) was one of the largest sectors within the EU-27's non-financial business economy (Sections B to J and L to N and Division95), particularly when measured in terms of output. Wholesale trade turnover was EUR4780 billion¹⁶¹ while value added was EUR549881 million, equivalent to 21.7% and 9.9% respectively of the non-financial business economy totals; this very high share of turnover reflects the nature of wholesaling, buying and reselling goods often in very large quantities. The 10.8 million strong workforce in the EU-27's wholesale trade sector accounted for 8.1% of the non-financial business economy total, while the 1.7 million wholesale trade enterprises contributed a broadly similar share (8.3%) of

¹⁶¹A billion is 1000 million.

the non-financial business economy enterprise population. As such, the wholesale trade sector can be characterised as having a large number of enterprises, of an average size in employment terms, with a slightly above average value added share and a particularly high level of turnover. Within **distributive trades** (SectionG), the wholesale trade sector contributed 58.1% of turnover, 49.6% of value added, 32.4% of employment and 28.5% of all distributive trades enterprises.

The **apparent labour productivity** of the EU-27's wholesale trade sector in 2009 was EUR51 thousand per person employed, above the non-financial business economy average of EUR41.6 thousand per person employed and more than 50% higher than the distributive trades average of EUR33 thousand per person employed. **Average personnel costs** per employee within the EU-27's wholesale trade sector were EUR34.7 thousand, which was also higher than the non-financial business economy average (EUR30.0 thousand) and the distributive trades average (EUR25.0 thousand). The **wage-adjusted labour productivity ratio** combines the two previous indicators and shows the extent to which value added per person employed covers average personnel costs per employee. Due to the particularly high productivity and only slightly elevated average personnel costs the EU-27's wholesale trade sector in 2009 had a higher wage-adjusted labour productivity ratio (146.5%) than the non-financial business economy average (138.8%) or the distributive trades average (133.2%).

In contrast, the very high turnover for the wholesale trade sector weighed down on the **gross operating rate** (which is the relation between the **gross operating surplus** and turnover), such that this averaged just 4.9% across the EU-27 in 2009, approximately half the non-financial business economy average (9.7%) and slightly below the distributive trades average (5.1%). Wholesale trade had the sixth lowest level of operating profitability (using this measure) among the NACE divisions within the EU-27's non-financial business economy, one place above **motor trades** (Division45).

Sectoral analysis

Among the activities that compose the wholesale trade sector, own-account wholesale trade (Groups46.2 to 46.9) accounted for 93.3% of the EU-27's wholesale trade value added in 2009, while wholesale on a fee or contract basis (Group46.1) accounted for the remainder; in terms of turnover the share for own-account wholesale trade was 95.4%.

The largest own-account wholesale trade subsector in the EU-27, in value added terms, was the wholesale trade of household goods (Group46.4) which contributed 28.1% of the sectoral total in 2009; this sector had the second largest workforce with a 23.0% share of wholesale trade employment. The subsector for other specialised wholesale trade (Group46.7) had the second highest value added share and a fractionally higher employment share than for household goods wholesaling – see Figure 1. Only two other subsectors contributed more than one tenth of wholesale trade value added or employment, namely food, beverages and tobacco wholesaling (Group46.3) and other machinery, equipment and supplies wholesaling (Group46.6).

The high apparent labour productivity (value added per person employed) figure for the wholesale trade sector was pulled upwards by information and communication (ICT) equipment wholesaling (Group46.5), household goods wholesaling and other machinery, equipment and supplies wholesaling. Although the remaining five subsectors recorded apparent labour productivity below the wholesale trade average they all reached levels that were above the average for distributive trades and for most subsectors apparent labour productivity was also above the non-financial business economy average – the exceptions were wholesale on a fee or contract basis and non-specialised wholesale trade (Group46.9).

In general, average personnel costs were quite different from one wholesale trade subsector to another. The EU-27's ICT equipment wholesaling subsector, which had the highest apparent labour productivity of all wholesale trade subsectors, also had the highest average personnel costs, EUR51.3 thousand per employee in 2009. The next highest level for this indicator was EUR10 thousand lower, at EUR41.1 thousand per employee for other machinery, equipment and supplies wholesaling. At the other end of the ranking, there were three subsectors that registered average personnel costs that were below the non-financial business economy average of EUR30.0 thousand per employee, namely agricultural raw materials and live animals wholesaling (Group46.2), food, beverages and tobacco wholesaling and non-specialised wholesale trade; average personnel costs for the last of these was also below the average for distributive trades.

In terms of the wage-adjusted labour productivity ratio, one wholesale trade subsector stood out, namely, wholesale on a fee or contract basis where the wage-adjusted labour productivity ratio within the EU-27 was

106.2% in 2009; this was the only wholesale trade subsector with a ratio below the 133.2% average for distributive trades. For the seven own-account wholesale trade subsectors, wage-adjusted labour productivity ranged from 136.6% for other machinery, equipment and supplies wholesaling (which was just below the non-financial business economy average) to 170.4% for non-specialised wholesale trade. For the gross operating rate, the position of the wholesale on a fee or contract basis subsector was reversed as it recorded the highest rate (8.5%) among the EU-27's wholesale trade subsectors in 2009, although this remained below the non-financial business economy average. Among the own-account wholesale trade subsectors, the gross operating rate ranged from 7.1% for household goods wholesaling to 3.1% for other specialised wholesale trade.

Country analysis

Germany contributed almost one quarter (24.1%) of the EU-27's value added in the wholesale trade sector in 2009 and was the largest Member State in value added terms for each of the seven own-account wholesale trade subsectors – with at least one fifth of the EU-27's value added in each case. France had the largest subsector for wholesale on a fee or contract basis, accounting for 18.1% of the EU-27 total.

Belgium and the Netherlands were the two most specialised Member States for wholesale trade, generating 13.9% and 13.1% respectively of their non-financial business economy value added in this sector in 2009. The least specialised Member States were Finland and the Czech Republic, where the wholesale trade sector contributed 7.7% and 7.5% respectively of national non-financial business economy value added. Among the non-member countries shown in Tables 4a and 4b, Switzerland and Norway showed specialisations outside the range recorded for the EU Member States: the share of wholesale trade in non-financial business economy value added was 14.6% in Switzerland while it was just 6.2% in Norway.

Wholesale on a fee or contract basis was particularly important in Slovenia where it contributed 2.8% of non-financial business economy value added in 2009, and this subsector was also relatively important in Slovakia and Italy where it contributed more than 1.0%. A number of other national specialisations stand out: Poland and Slovakia for non-specialised wholesale trade; the Netherlands, Ireland and Luxembourg for ICT equipment wholesaling; the Netherlands, Hungary, Bulgaria and Lithuania for agricultural raw materials and live animals wholesaling.

Among the Member States, wage-adjusted labour productivity ratios for wholesale trade in 2009 ranged from 129.0% in Spain to 199.9% in Poland with Bulgaria (222.4%) and Romania (236.2%) above this range and Italy (111.6%) below it. The gross operating rate of the wholesale trade sector ranged from 3.0% in France to 6.1% in both Poland and Belgium, with Germany recording a rate (6.8%) above this range, while Estonia (2.4%) and Lithuania (2.2%) were below it. In all of the Member States, the gross operating rate for wholesale trade was below the non-financial business economy average in 2009. However, when compared with the distributive trades average, several Member States recorded higher gross operating rates for wholesale trade, most notably Slovenia, Hungary and Ireland.

Data sources and availability

The analysis presented in this article is based on the main dataset for [structural business statistics \(SBS\)](#) which are disseminated annually. The series provides information for each Member State as well as a number of non-member countries at a detailed level according to the activity classification NACE. Data are available for a wide range of variables.

Context

This article presents an overview of statistics for the wholesale trade sector in the EU, as covered by NACE Rev.2 Division46. This division includes wholesale trade for own-account or on a fee or contract basis (commission trade) related to domestic wholesale trade as well as international wholesale trade (import/export). Wholesale is the resale (sale without transformation) of new and used goods to retailers, industrial, commercial, institutional or professional users, or other wholesalers; alternatively, it may involve acting as an agent or broker trading (buying or selling) merchandise with such clients. The principal types of businesses included

are merchant wholesalers, in other words, wholesalers who take title to the goods they sell, such as wholesale merchants or jobbers, industrial distributors, exporters, importers, and cooperative buying associations; also included are sales branches and sales offices (but not retail stores) that are maintained by producers apart from their production operations for the purpose of marketing their products and that do not merely take orders to be filled by direct shipments from the production operations. Also included are merchandise and commodity brokers, commission merchants and agents and assemblers, buyers and cooperative associations engaged in the marketing of farm products.

Wholesalers frequently physically assemble, sort and grade goods in large lots, break bulk, repack and re-distribute in smaller lots (for example, pharmaceuticals), store, refrigerate, deliver and install goods, engage in sales promotion or label design for their customers.

The activity is structured by first separating wholesalers on a fee or contract basis, and then distinguishing wholesalers based on their specialisation in terms of the different types of products that are for wholesale, with a final activity for wholesalers that sell a range of products and are therefore considered as unspecialised.

This NACE division is composed of eight groups:

- wholesale on a fee or contract basis (Group46.1);
- wholesale of agricultural raw materials and live animals (Group46.2);
- wholesale of food, beverages and tobacco (Group46.3);
- wholesale of household goods (Group46.4);
- wholesale of ICT equipment (Group46.5);
- wholesale of other machinery, equipment and supplies (Group46.6);
- other specialised wholesale (Group46.7);
- non-specialised wholesale trade (Group46.9).

The information presented in this article does not cover the wholesale of motor vehicles, motorcycles and their accessories (included as part of [motor trades](#) , Division45), the [renting and leasing](#) of goods (Division77), or the packing of solid goods and bottling of liquid or gaseous goods, including blending and filtering for third parties (which forms part of [office administrative, office support and other business support activities](#) , Division82).

Notes

Wood and paper production statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article introduces a [set of statistical articles](#) which analyse the structure, development and characteristics of the economic activities in the wood and paper manufacturing sector in the [European Union \(EU\)](#) . This sector covers [NACE Rev 1.1](#) Divisions 20 and 21, and its activities are treated in more depth in two further articles:

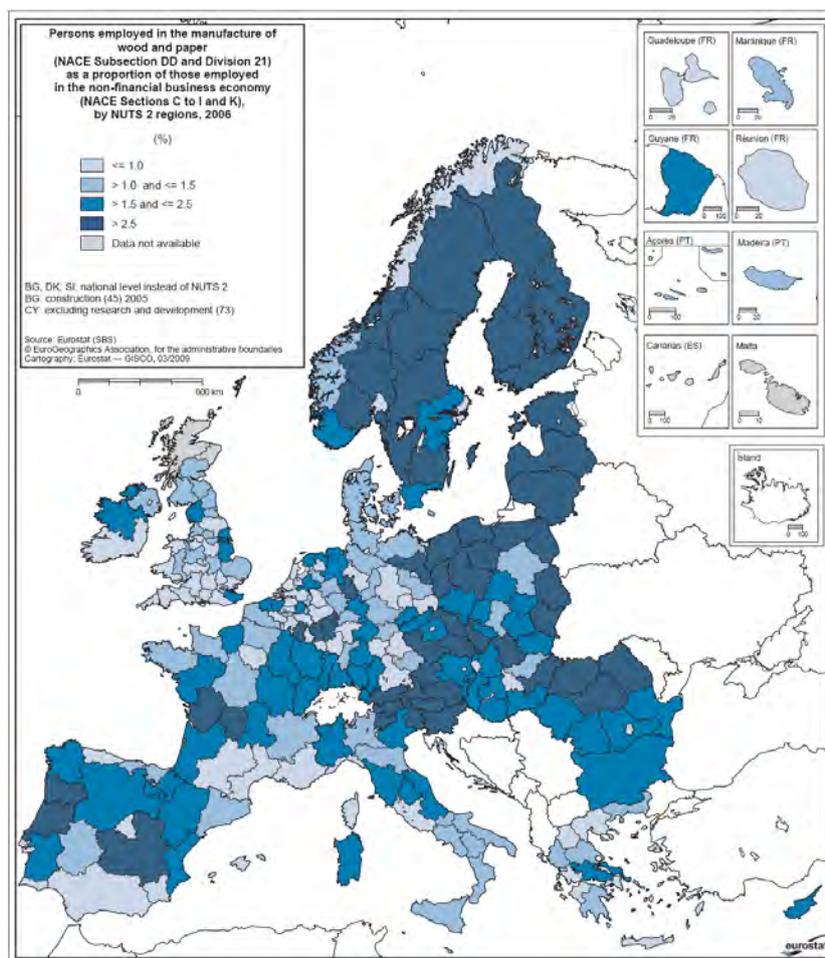

- the [manufacture of wood and wood products](#) , corresponding to NACE Division 20, which includes all stages of wood processing that follow on from the activity of forestry;
- the [manufacture of pulp, paper and paper products](#) , corresponding to NACE Division 21, which covers downstream activities that use output from the initial processing of wood.

Table 7: Manufacture of pulp, paper and paper products (NACE Division 21). Main indicators, 2006 (1).

It is important to underline that the wood and paper manufacturing sector does not include forestry, logging and related activities (NACE Division 02), and so these are not covered in this article.

Main statistical findings

Structural profile

The manufacture of wood and paper (NACE Divisions 20 and 21) was the main activity of 216.2 thousand enterprises across the EU-27 in 2006. These enterprises employed 2.0 million people in 2006, the equivalent of

1.5% of the total [non-financial business economy](#) (NACE Sections C to I and K) workforce. They generated EUR 78.3 billion of [value added](#), equivalent to a 1.4% contribution to the added value of the non-financial business economy.

The manufacture of wood and wood products was much larger than the manufacture of pulp, paper and paper products, in terms of both enterprise numbers (91.0% of all enterprises manufacturing wood and paper) and [employment](#) (64.0% of the sectoral workforce). However, it was a little smaller in terms of the value added that it generated (EUR 37.2 billion) in 2006, compared with EUR 41.1 billion for the manufacture of pulp, paper and paper products.

Wood and paper manufacturing enterprises in Italy accounted for a little over one fifth (21.2%) of all enterprises across the EU-27, far more than in any other Member State, including Germany (6.9%). However, it was the wood and paper manufacturing enterprises in Germany that generated by far the most value added (20.9% of the EU-27 total in 2006), far ahead of Italy (12.2%) and then France (10.0%). None of these Member States were particularly specialised in wood and paper manufacturing activities, as the relative contributions of this sector to non-financial business economy value added was close to or below the EU-27

average in each of the three main producing countries. In these relative terms, Finland was by far the most specialised Member State, as the relative contribution of wood and paper manufacturing to the non-financial business economy value added was about four and a half times the EU-27 average. Estonia, Latvia and Sweden were also relatively specialised in these activities in 2006.

In terms of the contribution of the wood and paper manufacturing sector to employment within the non-financial business economy, the region of Detmold (Germany) was the most specialised in this activity; 9.1% of its non-financial business economy workforce were employed in wood and paper manufacturing activities in 2006. The next most specialised regions were found in Finland and Sweden, with high degrees of specialisation also recorded in the [Baltic Member States](#) (each considered as one region at the level of detail shown in the map), as well as parts of Romania, the Czech Republic, Italy, Austria and Slovenia.

The evolution of EU-27 [production indices](#) for wood and wood products manufacturing on the one hand, and pulp, paper and paper products manufacturing on the other, were relatively similar in the ten years through until 2007. For both of these activities, [output](#) growth was relatively strong in the period between 1997 and 2000 (particularly in the case of wood and wood products), before a decline in production was observed in 2001. This was then followed by a relatively steady upswing (albeit with a temporary fall in the output of pulp, paper and paper products in 2005). The growth in output over the ten year period through until 2007 averaged 1.8% per year for pulp, paper and paper products and 2.4% per year for wood and wood products, both of these rates were relatively similar to the average recorded for the whole of the industrial economy (2.1% per year).

There were distinct differences in enterprise size structure between the two subsectors. The pulp, paper and paper products subsector in the EU-27 was dominated by [medium-sized](#) (those employing between 50 and 249 people) and [large enterprises](#) (those employing more than 250 people); these two size classes accounted for a combined share of 78.8% of this subsector's workforce. In contrast, micro (those employing less than 10 persons) and small enterprises (those employing 10 to 49 persons) together accounted for the majority (61.0%) of employment within the wood and wood products subsector.

These relative differences in the size class structure between the two subsectors may, at least in part, explain some of the differences observed in [productivity](#) levels between the two activities. EU-27 apparent labour productivity was highest among large enterprises within the pulp, paper and paper products subsector (EUR 73.3 thousand per person employed) in 2006. At the other end of the range, each person employed in a micro enterprise in the wood and wood products subsector generated an average of EUR 20.0 thousand of added value.

Employment characteristics

The workforce of the EU-27

's wood and paper manufacturing sector displayed a particularly high propensity to employ men; in 2007, almost four fifths (79.0%) of the workforce were men, compared with a little less than two thirds (64.9%) across the non-financial business economy as a whole. This characteristic was common across all of the Member States

for which data are available¹⁶².

The overwhelming majority (94.6%) of the wood and paper manufacturing workforce were engaged full-time across the EU-27 in 2007, a notably higher proportion than the non-financial business economy average (85.7%). These working-time characteristics were common to all of the Member States with the exception of Hungary, where the proportion of part-time work (6.8%) in wood and paper manufacturing was almost three percentage points higher than the non-financial business economy average (3.9%).

The age profile of the EU-27's wood and paper manufacturing workforce was broadly similar to that of the non-financial business economy in 2007, albeit with a slightly lower proportion of persons under 30 years of age (22.0% compared with 24.3%). Among the Member States, however, the proportion of young workers in the wood and paper manufacturing sector was significantly lower than national non-financial business economy averages in Denmark (15.6% compared with 27.1%) and the Netherlands (19.2% compared with 30.3%), and to a lesser degree in France, the United Kingdom, Sweden and Cyprus.

Expenditure, productivity and profitability

The structure of **operating costs** in the EU-27's wood and paper manufacturing sector was similar to that observed for the whole of the non-financial business economy in 2006; the bulk (82.1%) of operating expenditure was accounted for by purchases of goods and services.

Investment across the EU-27 in the wood and paper manufacturing sector accounted for 1.4% of the non-financial business economy total in 2006, which was the same proportion as the relative share of wood and paper manufacturing in total value added. The relative importance of investment within wood and paper manufacturing activities was highest in Finland (6.3% of total investment), Estonia (4.2%) and Latvia (4.1%), three of the Member States that were most specialised in the manufacture of wood and paper.

Investment in tangible goods covered 18.6% of the value added that the wood and paper manufacturing sector generated in the EU-27 in 2006, a very similar proportion (18.4%) to that noted across the whole of the non-financial business economy. Among the Member States, the **investment rate** for wood and paper manufacturing was particularly high in Latvia (66.3%) and Lithuania (53.5%); these rates were also relatively high in relation to national investment rates for the non-financial business economy (47.1% and 39.9%).

The apparent **labour productivity** of the wood and paper manufacturing sector across the EU-27 was EUR 39.4 thousand per person employed in 2007, about 10% less than the non-financial business economy average. However, apparent labour productivity of the pulp, paper and paper products subsector was EUR 57.5 thousand per person employed, which was about double the level recorded for the wood and wood products manufacturing subsector (EUR 29.3 thousand per person employed). In all of the Member States for which information is available¹⁶³, with the notable exception of Ireland, the apparent labour productivity of the pulp, paper and paper products manufacturing subsector was higher (often considerably so) than productivity within the wood and wood products subsector.

Average **personnel costs** in the EU-27's pulp, paper and paper products manufacturing subsector (EUR 37.7 thousand per employee) were also higher than those experienced across the wood and wood products manufacturing subsector (where each employee cost about 20% less). As a result, the difference in productivity levels when measured in wage adjusted terms narrowed, with the ratio for the pulp, paper and paper products manufacturing sector (152.5%), almost identical to the non-financial business economy average (151.1%), while that for the wood and wood products manufacturing subsector was somewhat lower (140.1%).

The **gross operating rate** (which is one measure of **profitability**) of the wood and paper manufacturing sector of the EU-27 was 9.8% in 2006, a little below the corresponding rate for the non-financial business economy (10.8%). Whilst this pattern was repeated across most of the Member States, the profitability of the wood and paper manufacturing sector was about half the non-financial business average in the United Kingdom (7.6% compared with 14.4%), while in Portugal it was about higher (13.3% compared with 9.2%). Whereas the profitability of the EU-27's pulp, paper and paper products subsector had been higher than that of the wood and wood products subsector in 2002 (12.6% and 9.5% respectively), the difference between these two rates subsequently narrowed and reversed, with the gap widening in 2006 (9.1% and 10.7% respectively).

¹⁶²Luxembourg and Malta, not available.

¹⁶³Cyprus, the Netherlands and Poland, 2005; Luxembourg and Malta, not available.

External trade

The EU's internal market accounted for approximately three quarters (74.8%) of the EU-27's trade in wood and paper products (CPA Divisions 20 and 21) in 2007. Trade in wood and paper products with the rest of the world, however, recorded a **surplus** of EUR 6.2 billion in 2007, with **exports** valued at EUR 30.4 billion and **imports** valued at EUR 24.2 billion. More specifically, the overall surplus was derived from pulp, paper and paper products (a surplus of EUR 8.3 billion) as there was a deficit (EUR 2.1 billion) for wood and wood products. The trade surplus for pulp, paper and paper products grew considerably (58.4% overall) in the period between 2002 and 2007, during which time the **trade deficit** for wood and wood products also widened (from EUR 0.4 billion in 2002).

Exports of wood and paper products represented a significant share of all industrial exports in just a handful of Member States; in Finland and Latvia they represented a fifth of industrial exports in 2007, while in Estonia and Sweden they accounted for a little more than 10% of the total, significantly more than their average share (2.6%) across the whole of the EU-27. Finland and Sweden had the highest trade surpluses for wood and paper products in 2007 (EUR 11.2 billion and EUR 10.8 billion respectively), with surpluses also recorded in Germany (EUR 5.5 billion) and Austria (EUR 4.2 billion). In contrast, the United Kingdom had by far the largest trade deficit for wood and paper products (EUR 9.5 billion).

Although the United States remained the largest export market for EU-27 wood and paper products (accounting for an 11.1% share of extra-EU exports) in 2007, this share was down sharply on the corresponding value for 2006 (14.2%); the relative importance of exports to Russia and Norway grew between 2006 and 2007. Imports of wood and paper products into the EU-27 from China continued to grow, overtaking the United States for the first time in 2007, with a 14.8% share of all EU-27 wood and paper imports. Brazil and Canada were also relatively important providers of wood and paper products to EU-27 markets; they accounted for 11.7% and 7.1% respectively of extra-EU imports in 2007 (significantly higher than their shares for all industrial goods, 1.9% and 1.5% respectively).

Data sources and availability

The main part of the analysis in this article is derived from **structural business statistics (SBS)**, including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include **short-term statistics (STS)**, the **Labour force survey (LFS)**, the **COMEXT** database for external trade and **PricewaterhouseCoopers' 2008 Global Forest, Paper & Packaging Industry Survey**.

Context

The multi-functional role of forests is an area of increasing global scrutiny. Wood is an important, renewable economic resource, while forests are increasingly recognised for the environmental role they play in climate regulation, biodiversity, air, soil and water quality, as well as their recreational function.

Building on the EU Forest Action Plan (**COM(2006) 302 final**) for 2007 to 2011 and its 18 key actions for sustainable forest management and the improved long-term competitiveness of its associated industries, the EU has been active in pushing for international commitment to end global forest cover loss by 2030 as part of a new 'forestry package'. This package includes proposals from the European Commission that look to address some of the challenges of deforestation and forest degradation in order to tackle climate change and biodiversity loss (**COM(2008) 645 final**), as well as laying down obligations for operators who place timber and timber products on the market (**COM(2008) 644 final**). These would include obliging market traders to certify that the timber and timber products they sell have been harvested according to the relevant laws of the country of origin. It is also proposed that a new global financial fund, known as the Global Forest Carbon Mechanism (GFCM), be made available to developing countries as a reward for emissions reductions achieved by taking action to reduce deforestation and forest degradation. The EU's **Emissions Trading Scheme** would

be a major source of funding for any GFCM, whereby EUR 2.5 billion could be provided to the fund by 2020 through 5% of auctioning revenues. Furthermore, those governments that sign-up to a global climate change deal could also be allowed to use so-called deforestation credits towards their individual CO2 reduction commitments.

These proposals, as well as an EU Forest Action Plan could have implications for the diverse wood and paper manufacturing sector in the EU. In part, this may reflect the varied size structure of enterprises within the two subsectors: the pulp, paper and paper products subsector is dominated by large, multinational enterprises, many of which are in the [Nordic Member States](#) ; whereas, the wood and wood products subsector is characterised by relatively small-scale enterprises that are predominantly privately-owned and serve local or national markets.

Notes

Wood and wood product statistics - NACE Rev. 1.1

Data from January 2009, most recent data: Further Eurostat information, Main tables and Database

This article belongs to a [set of statistical articles](#) which analyse the structure, development and characteristics of the various economic activities in the [European Union \(EU\)](#). The present article covers wood and wood products, corresponding to [NACE Rev 1.1 Division 20](#), which is part of the [wood and paper manufacturing](#) sector. The activities covered in this article are:

- the initial processing stages of sawing and planing of wood (corresponding to NACE Group 20.1);
- semi-processed wood products, such as the manufacture of boards and panels (NACE Group 20.2);
- builders' carpentry and joinery (NACE Group 20.3);
- finished products such as wooden containers (NACE Group 20.4);
- other wood products, including household goods made from wood (NACE Group 20.5).

Note that furniture manufacturing (NACE Group 36.1), whether from wood or other materials, is not covered here, but in the article on [furniture production statistics](#). Nor does this article include forestry, logging and related activities (NACE Division 02).

(1) Cyprus, Netherlands and Poland, 2005; unless otherwise stated, values refer to EUR million; number of enterprises and number of persons employed are given in thousands; average personnel costs and apparent labour productivity are given in EUR thousand per person; wage adjusted labour productivity, gross operating rate and investment are ratios expressed as percentages.

Source: Eurostat (SBS)

Table 4: Manufacture of wood and of products of wood and cork, except furniture; manufacture of articles of straw and plaiting materials (NACE Division 20). Main indicators, 2006 (1)

There were 196.8 thousand enterprises across the EU-27 for which wood and wood products manufacturing (NACE Division 20) was their main activity. These enterprises generated EUR 37.2 billion of value added in 2006, a little under one half (47.5%) of the total value added generated in the wood and paper manufacturing sector. They also employed just over one and a quarter million people across the EU in 2006, about two thirds (64.0%) of the sectoral workforce.

Within the wood and wood products manufacturing sector, the largest activity at the NACE group level was the manufacture of builders' carpentry and joinery (NACE Group 20.3), which includes the manufacture of wooden goods likes beams, rafters, door, windows and parquet flooring for the construction industry; it contributed EUR 16.4 billion of value added (44.1% of the total for wood and wood products manufacturing) and employed 579.0 thousand persons across the EU-27 (45.6% of the wood and wood products manufacturing workforce). The second largest activity, in terms of both value added and employment was that of sawmilling, planing and the impregnation of wood (NACE Group 20.1), which is the first stage in the processing of wood; this activity generated a little less than a quarter (23.1%) of EU-27 value added (EUR 8.6 billion) and employed about one in every four (24.2%) persons within the wood and wood products manufacturing workforce. The remaining third (32.7%) of value added generated across wood manufacturing, a combined EUR 12.1 billion, was generated through the manufacture of veneer sheets, plywood, laminboard, particle board, fibre board and other panels and boards (NACE Group 20.2), other products of wood (NACE Group 20.5) and wooden containers (NACE Group 20.4).

The wood and wood products manufacturing sector in Germany generated EUR 6.6 billion of value added in 2006, the largest contribution (17.7%) to the EU-27 total. A further two fifths (43.0%) of the value added generated across the EU-27's wood and wood products manufacturing sector came from the output of Italy, the United Kingdom, France and Spain. However, it was the [Baltic Member States](#) that were the most specialised in this activity. Indeed, in Latvia and Estonia wood and wood products manufacturing contributed almost 4% of the value added generated across their respective [non-financial business economies](#), which was a little more than five and a half times the average contribution made by these activities across the EU-27 as a whole.

Among the subsectors covered, the strongest rise in EU-27 output during the ten-year period through to 2007 was recorded for veneer sheets, plywood, laminboard, particle board, fibre board and other panels and boards (where growth averaged 3.4% per year in the EU-27). In contrast, there was a relatively sharp decline (-3.4% per year between 2000 and 2007) for the production of other wood products, articles of cork, straw and plaiting materials.

Against a background of progressive increases in the [output](#) of wood and wood products within the EU-27 (averaging 2.4% per year during the period 1997 to 2007), there were particularly high gains recorded in Luxembourg (12.4% per year), Poland (8.1% per year), Romania (6.3% per year), Latvia (5.8% per year) and Austria (5.7% per year).

Expenditure and productivity

Average [personnel costs](#) in the wood and wood products sector were relatively low in the EU-27, as they averaged EUR 20.9 thousand per employee in 2006, which was 23.7% less than for the whole of the wood and paper manufacturing sector. As a proportion of total [operating expenditure](#), however, personnel costs in the wood and wood products sector accounted for a slightly higher share (18.9%) than the corresponding figure for wood and paper manufacturing (17.9%).

Average personnel costs were particularly low in the sawmilling, planing and impregnation of wood subsector (EUR 17.1 thousand per employee) and the other wood products, articles of cork, straw and plaiting materials manufacturing subsector (EUR 17.7 thousand per employee). In the case of the other wood products, articles of cork, straw and plaiting materials manufacturing subsector, personnel costs nevertheless accounted for over one fifth (21.4%) of total operating expenditure, suggesting that this is a relatively low-wage, labour-intensive activity.

The apparent [labour productivity](#) of the wood and wood products manufacturing sector in the EU-27 was about one quarter (25.8%) less than the average recorded for the whole of the wood and paper manufacturing sector in 2006. There was a considerable spread, however, in apparent labour productivity levels; at one extreme, the manufacture of other wood products, articles of cork, straw and plaiting materials subsector reported that each person employed generated an average of EUR 22.5 thousand of added value, which was about half the level recorded within the veneer sheets, plywood, laminboard, particle board, fibre board and other panels and boards subsector (EUR 45.1 thousand per person employed).

With both average personnel costs and apparent labour productivity about a quarter less than across the wood and paper manufacturing sector as a whole, wood and wood products manufacturing recorded a wage-adjusted labour productivity ratio that was similar to that for the whole of wood and paper manufacturing (140.1% compared with 144.0% in 2006). Wage adjusted labour productivity ratios for both the manufacture of veneer sheets, plywood, laminboard, particle board, fibre board and other panels and boards subsector (172.0%) and the sawmilling, planing and impregnation of wood subsector (164.0%) were notably higher.

Data sources and availability

The main part of the analysis in this article is derived from [structural business statistics \(SBS\)](#), including core, business statistics which are disseminated regularly, as well as information compiled on a multi-yearly basis, and the latest results from development projects.

Other data sources include the [PRODCOM](#) statistics on the production of manufactured goods.

Context

The multi-functional role of forests is an area of increasing global scrutiny. Wood is an important, renewable economic resource, while forests are increasingly recognised for the environmental role they play in climate regulation, biodiversity, air, soil and water quality, as well as their recreational function.

Building on the EU Forest Action Plan ([COM\(2006\) 302 final](#)) for 2007 to 2011 and its 18 key actions for sustainable forest management and the improved long-term competitiveness of its associated industries, the EU has been active in pushing for international commitment to end global forest cover loss by 2030 as part of a new 'forestry package'. This package includes proposals from the European Commission that look to address some of the challenges of deforestation and forest degradation in order to tackle climate change and biodiversity loss ([COM\(2008\) 645 final](#)), as well as laying down obligations for operators who place timber and timber products on the market ([COM\(2008\) 644 final](#)). These would include obliging market traders to certify that the timber and timber products they sell have been harvested according to the relevant laws of the country of origin. It is also proposed that a new global financial fund, known as the Global Forest Carbon Mechanism (GFCM), be made available to developing countries as a reward for emissions reductions achieved by taking action to reduce deforestation and forest degradation. The EU's [Emissions Trading Scheme](#) would be a major source of funding for any GFCM, whereby EUR 2.5 billion could be provided to the fund by 2020 through 5% of auctioning revenues. Furthermore, those governments that sign-up to a global climate change deal could also be allowed to use so-called deforestation credits towards their individual CO2 reduction commitments.

These proposals, as well as an EU Forest Action plan could have implications for the diverse wood and paper manufacturing sector in the EU. In part, this may reflect the varied size structure of enterprises within the two subsectors: the pulp, paper and paper products subsector is dominated by large, multinational enterprises, many of which are in the Nordic Member States; whereas, the wood and wood products subsector is characterised by relatively small-scale enterprises that are predominantly privately-owned and serve local or national markets.

In January 2008, the [European Commission](#) released an energy and climate change package that includes a draft Directive on Renewable Energy Sources ([COM\(2008\) 19 final](#)). The Directive aims to achieve a 20% mandatory share of renewable energy (including at least 10% of transport fuel consumption from biofuels, which would include timber and woodchips) in final energy consumption by 2020. This has led to some concerns about growing wood shortages and resultant price rises for the EU's wood and paper sector. The [European Commission's Enterprise Directorate-General](#) hopes the EU's woodworking industries will be able to better compete in the future through the promotion of greater skills, higher levels of training, innovation, the use of new technology and better networking between [small and medium-sized enterprises](#) in order to improve supply and distribution chains.

Short-term statistics; tourism

Short-term business statistics introduced

Short-term business statistics, often simply called short-term statistics and abbreviated as STS, describe the most recent developments of the economies of the [European Union \(EU\)](#) and its Member States. STS indicators are important tools for formulating and monitoring the economic and monetary policy of the EU and the [euro area](#) ; they are in great demand by the [European Commission](#) and [European Central Bank \(ECB\)](#) , national governments and central banks, companies and financial markets.

STS indicators are generally published with a monthly frequency. They cover the 27 EU Member States, but also provide aggregate data for the EU and the euro area. In order to be relevant and to reflect current developments with short delays, STS focus on four major domains (industry, construction, retail trade and other services), for which the following indicators or variables are compiled:

- Industry:
 - [Production](#)
 - Turnover (domestic and non-domestic)
 - [New orders](#) (domestic and non-domestic) (The publication of this indicator was discontinued with the end of the reference year 2011.)
 - Number of persons employed
 - Hours worked
 - Gross wages and salaries
 - [Output prices \(domestic and non-domestic\)](#)
 - [Import prices](#)
- Construction:
 - Production (of buildings and of civil engineering)
 - Number of persons employed
 - Hours worked
 - Gross wages and salaries
 - [Construction costs \(material costs wage costs\)](#)
 - [Construction permits](#)
- Retail trade and repair:
 - Turnover
 - Number of persons employed
 - [Deflator](#) of sales
- Other services:
 - Turnover
 - Number of persons employed
 - [Services producer price index \(SPPI\)](#)

These four domains are defined in relation to the general classification of economic activities, the [NACE Rev.2](#) (Statistical classification of economic activities in the European Community, second revision). For STS purposes industry covers mining and quarrying, manufacturing, electricity, gas and water-supply and similar businesses. Construction covers residential and non-residential buildings and civil engineering. Retail trade covers total retail trade with the exception of cars and motorcycles. Other services cover a diverse array of activities such as sales of motor vehicles, transport, information and communication and business services but not financial services.

Smaller countries generally do not report data in the same level of detail as bigger countries. Moreover, not all activities listed in the NACE Rev. 2 under the headings industry, construction, retail trade/repair and services

are fully reflected in all STS indicators.

STS indicators represent the general economic trend in the form of indices ([time series](#)), i.e. they show the changes of a variable (production, turnover etc.) over time but not the absolute amount or monetary value of the variable. Generally STS indices have a fixed base year. The index value for any given period in a time series represents the change of the underlying variable compared to a single fixed base which is the same for all indices in that time series. In order to reflect structural changes in the economies the base year is adjusted every five years.

In line with the principle of subsidiarity, STS indicators for Member States are calculated by the national statistical institutes. Depending on the specific situation in a country, data may come from from different sources (usually surveys and administrative data). Where necessary to ensure comparability, data transmitted to [Eurostat](#) are adjusted so they fit into a common and harmonized methodological framework. It should be noted that national indicators published by Eurostat according to this common methodology are not necessarily identical to the results published by national statistical institutes for national purposes.

Economies (e.g. a single country, the European Union or the euro area) do not develop in a linear way. Over a [business cycle](#) periods of strong growth change with periods of stagnation or even periods of negative growth. The [analysis of time series](#) of the economic development aims at identifying the various components of the economic development, i.e. wants to find out to what extent changes in a time series follow a stable long term [trend](#) , whether they are a cyclical development around a trend, whether they are a result of seasonal influences or to what extent they are irregular und unpredictable.

The various indicators covered by STS do not represent the general economic development in a synchronised way. Some indicators such as the new orders move ahead of changes in the overall economic conditions ([leading indicator](#)), some, like production, move largely in parallel with it ([coincident indicator](#)) and some, like employment, only change when the general conditions have already altered ([lagging indicator](#)).

In order to increase comparability between different periods time series are adjusted for [calendar effects](#) ([working-day adjustment](#)) and seasonal effects ([seasonal adjustment](#)). Without such adjustments a figure for May (a month with many public holidays) might wrongly indicate a decline of economic activity. Similarly a comparison between countries, e.g. between Sweden (holidays in June) and France (holidays in August) could be misleading.

The legal base for the European short-term business statistics is [Regulation 1165/98](#) , as amended by [Regulation 1158/2005](#) and other implementing and amending regulations.

Short-term business statistics - legal base

This article gives an overview of the legal texts underlying the calculation and dissemination of [European Union \(EU\) short-term statistics \(STS\)](#) . It starts off with the first and most important one, [Council Regulation 1165/98](#) of 19 May 1998, the so-called STS Regulation.

Since 1998 many aspects of the STS Regulation have been amended in subsequent Regulations (see below), but a major change took place in 2005 with [Regulation 1158/2005](#)

Basis: the 1998 STS Regulation

[Regulation 1165/98](#) in its present form outlines as a general aim the establishment of a common European framework for the analysis of the [business cycle](#) by collecting information on the supply and demand, on production factors and prices (article 1).

It defines and limits the principal scope of STS by stipulating that STS shall cover market activities of [statistical units](#) in mining, quarrying, manufacturing, wholesale, retail trade, services, and several other economic sectors which are identified by reference to the [Statistical classification of economic activities in the European Community \(NACE rev. 2\)](#) (article 2) and how such a collection should take place. In particular it allows Member States to use different sources to obtain the data (article 4).

The Regulation also defines how often data have to be produced (periodicity, article 5) and in what detail (article 6 and annexes, see below). It prescribes that data are to be processed according to common rules to ensure comparability (article 7), how they are transmitted to the EU's statistical office [Eurostat](#) (article 8) and how confidentiality of sensitive data is guaranteed (article 9). The Regulation demands that national statistical authorities ensure the quality of the data (i.e. that they truly reflect real developments, article 10) and that the [weighting](#) system of indicators is renewed every five years (article 11).

Apart from such strictly statistical issues the STS Regulation also deals with a number of procedural questions. It demands the publication of a manual at regular intervals (article 12) and also the presentation of regular reports on the costs and benefits of STS (article 14). Transition periods during which new STS rules have to be implemented must not be longer than five years (article 13). Concrete implementing measures are decided with a special committee procedure regulating the roles of the [European Commission](#) and the Member States (articles 17, 18). The Regulation also ensures coordination within Member States (article 15) and foresees the possibility of pilot studies (article 16).

Annexes to the STS Regulation

Annexes A – D of [Regulation 1165/98](#) (article 3) stipulate in detail the specific requirements for the production of the statistical variables under the STS Regulation. The annexes provide detailed requirements as regards:

- scope (economic activities);
 - [observation unit](#) (statistical unit from which data are collected);
- list of variables;
- form (whether data are to be transmitted as an index, as absolute values, [seasonally adjusted](#) etc.);
 - [reference period](#) (monthly or quarterly data);
 - level of detail;
 - deadlines for data transmission (from Member States to Eurostat);
 - pilot studies;
 - first reference year;
 - transition period.

Policy backgrounds and historical overview

1998

The evolution of short-term statistics has followed that of European Union policies. For the first 40 years, most Community policies were structural and accordingly EU statistics mainly represented structural facts which also meant that they were in most cases only published annually or sometimes even less frequently. With the gradual development and implementation of the [economic and monetary union](#), short-term statistics were needed in order to manage monetary policy.

[Council Regulation 1165/98](#), the STS Regulation, established the legal basis for the production of short-term indicators for [manufacturing industry](#), construction, [retail trade](#) and services. The 1998 Regulation already provided most of the basic STS elements described above.

2001

In 2001 two important implementing measures for short-term statistics were adopted:

- [Regulation 586/2001](#) defined [main industrial groupings \(MIGs\)](#) for the purpose of short-term statistics;
- [Regulation 588/2001](#) provided more precise definitions for the variables covered by STS, e.g. production, turnover, sales etc.

2005

By the early 2000s, the European Commission and the [European Central Bank \(ECB\)](#) were focusing on short-term developments in the newly-created [single market](#) and the [euro area](#). It was clear that better data were needed. In addition, the ever-increasing importance of services in European economies could not remain largely unmeasured. In 2002 Eurostat started to take initiatives towards amending the STS Regulation, with two major objectives: to accelerate the transmission of data and to include output prices for services, missing in the 1998 Regulation. The STS Regulation was amended on 6 July 2005 with [Regulation 1158/2005](#) requiring Member States to provide a [service producer price index \(SPPI\)](#) (output price index for services) broken down by type of service, on a quarterly basis, from 2006 onwards (although there longer transition periods were foreseen for smaller countries). In addition to the output price index for services a new indicator for [industrial import prices](#) was introduced.

[Regulation 1158/2005](#) modified several articles of the 1998 STS Regulation. It also introduced the possibility of European sample schemes as one method to obtain the data for some of the variables under STS. The details for European sample schemes in the framework of STS were later set out more specifically in [Regulation 657/2007](#) of 14 June 2007 (see below).

2006-2009

- [Regulation 1503/2006](#) replaced [Regulation 588/2001](#) (see above) and provided new definitions of STS indicators. For the construction sector (annex B) the new orders received, new orders received for [building construction](#) and new orders received for [civil engineering](#) were deleted from the list of STS indicators.
- [Regulation 1502/2006](#) provided new rules with regard to derogations for individual Member States, in order to facilitate the introduction of the changes required by [Regulation 1158/2005](#).
- [Regulation 656/2007](#) amended [Regulation 586/2001](#) (see above) on main industrial groupings in order to take into account the transition from the classification of economic activities NACE Rev.1 to NACE Rev.2.
- [Regulation 657/2007](#) implemented rules for the use of European sample schemes in STS. European sample schemes could be used for the indicators industrial non-domestic new orders, industrial output prices of the non-domestic market and for industrial import prices.

- [Regulation 472/2008](#) specified a number of technical details related to the introduction of the new statistical classification of economic activities, NACE Rev. 2, into short-term statistics. These details included the first base year to be applied (2005), and the features of historical data recalculated in terms of NACE Rev. 2 (level of detail, form, first reference period, reference period)
- [Regulation 1178/2008](#) introduced further adaptations for European sample schemes with relation to the new economic classification.
- [Regulation 329/2009](#) introduced hours worked and gross wages and salaries for retail trade and services as new short-term statistics indicators (to be provided from 2013 onwards, with time series going back to at least 2010).

Other legal acts impacting STS

Some other Regulations, although not specifically drafted in the context of short-term statistics, nevertheless had important repercussions for their collection and calculation:

- [Regulation 696/93](#) of 15 March 1993 on the statistical units for the observation and analysis of the production system in the Community;
- [Regulation 1893/2006](#) of 20 December 2006 establishing the statistical classification of economic activities NACE Revision 2 and amending Council Regulation (EEC) No 3037/90 as well as certain EC Regulations on specific statistical domains Text with EEA relevance.

Short-term business statistics - observation units

A common definition of [observation units](#) (also called statistical units), i.e. the units about which data are collected, is a prerequisite for comparable European statistics. [Council Regulation \(696/93](#) of 15 March 1993 on the statistical units for the observation and analysis of the production system in the Community defines eight different types of statistical units.

Short-term business statistics use two of these types:

- for industry and construction the *kind-of-activity-unit (KAU)* ;
- for retail trade and services the *enterprise* .

The [short-term business statistics Regulation](#) foresees the possibility of exceptions: for industry and construction the enterprise might be used instead of the KAU for those enterprises with few persons employed in secondary activities.

Enterprise

An **enterprise** is an organisational unit producing goods or services which has a certain degree of autonomy in decision-making. An enterprise can carry out more than one economic activity and it can be situated at more than one location. An enterprise is not necessarily a sole legal unit but can be a group of legal units.

Kind-of-activity unit

The **kind-of-activity unit (KAU)** is a part of an enterprise. The KAU groups together all the offices, production facilities etc. of an enterprise which contribute to the performance of a specific economic activity defined at class level (four digits) of the European classification of economic activities ([NACE Rev. 2.](#)) For example a kind-of-activity unit might be the combination of all parts of a metal producing enterprise that produce copper (class 24.44 in NACE Rev. 2); within the same enterprise there might be another KAU consisting of those parts that produce aluminium (class 24.42 in NACE Rev. 2). In order to statistically subdivide enterprises into KAUs the enterprise's information system must be capable of indicating or calculating for each KAU at least the value of production, intermediate consumption, manpower costs, the operating surplus and employment and gross fixed capital formation.

The purpose of the KAU is to improve the homogeneity of statistical surveys by economic activity. In the above example, without the use of KAUs, it might be necessary to classify the enterprise either as a copper manufacturer or as an aluminium manufacturer. In such a way rather diverse enterprises might be considered to engage in the same economic activity which would make statistical results less clear and comparable.

Short-term business statistics - quality and scope

This article presents various quality aspects of [European Union \(EU\) short-term statistics \(STS\)](#) : their timeliness, scope, accuracy, reliability and various other quality indicators.

It is part of a set of [background articles](#) treating various methodological aspects of short-term business statistics.

Timeliness and punctuality

Indicator	Periodicity	STS-Regulation deadlines	Dissemination of EU totals
Industrial production	Monthly	40	42
Industrial output prices (domestic market)	Monthly	35	34
Industrial new orders	Monthly	50	55
Industrial import prices	Monthly	45	34
Production in construction	Monthly	45	49
Turnover in retail trade and repair	Monthly	30	35
Turnover in other services	Quarterly	60	61
Service output prices	Quarterly	90	n.a.
Building Permits	Quarterly	90	90

Table 1: Timeliness of short-term business statistics (days between end of reference period and data dissemination of European results)

For short-term statistics the early availability of data is of central importance. For five STS indicators results are published in a [monthly news release](#) between 35 and 55 days after the end of the reference period (e.g. data for retail trade turnover in July 2011 became available on 5 September 2011).

The [European regulation on short-term statistics](#) (also see [the article on the legal base](#)) already included deadlines for the delivery of national data to Eurostat . With the amending [Regulation 1158/2005](#) these deadlines have been considerably shortened for most indicators (see Table 1, 3rd column). Only few days are needed for the calculation and dissemination of European results, e.g. [aggregates](#) for [EU-27](#) or the [euro area](#) (see Table 1, last column). Users are informed well in advance about the publication dates of the news releases by the [release calendar](#) on the Eurostat website. In 2010, all dates announced in the calendar were met.

Scope and compliance

The [legal base for short-term business statistics \(STS\)](#) is [Regulation 1165/98](#) and subsequent modifying acts. Currently STS covers a total of [43 different indicators](#) , including [production](#) , turnover, prices and employment measures for four different areas of the economy (industry, construction, retail trade, services).

Member States' compliance with the short-term statistics Regulation in terms of reliability, timeliness, coherence and comparability is monitored by Eurostat every six months and shows a high level of compliance and constant improvement. Every three years the general quality of short-term business statistics is assessed and

the results are [reported to the European Parliament and the Council](#) .

Coherence and comparability

Regulation 1165/98 and related acts have introduced a set of common STS definitions which are applied by all Member States. The [methodological framework](#) established by the Regulation is continuously improved by mutual consultations and special thematically focused task forces. Methodologies do not have to be identical in Member States. In accordance with the principle of subsidiarity Member States are free to decide on the most efficient and effective ways of collecting and processing data in order to take into account national differences, e.g. in size, economic structure and availability of administrative data. Eurostat also works together with other international organisations, especially the [OECD](#) , in order to increase the comparability of data and methods beyond the European Union.

Revisions

Indicator (seasonally adjusted growth rates)	Average difference between 1st and 2nd publication
Industrial production	0.1
Industrial output prices of the domestic market	0.0
Industrial new orders	-0.1
Production in construction	0.0
Volume of retail trade	0.1

Table 2: Size of revisions of STS indicators (difference between growth rates at first and second publication)

First results of short-term indicators are partly based on estimated and incomplete data. For this reason results change between first, second and even subsequent publications.

Over time survey results become more complete because missing or late respondents have been added. Other reasons why data are revised are [seasonal adjustment](#) , benchmarking, new and/or improved data sources, and corrections of errors or methodological changes. Nevertheless, the size of revisions of short term indicators is generally rather limited, especially at the aggregate EU level and for the euro area. Table 2 presents for the five short-term indicators published monthly in special [news releases](#) the changes between the first and the second publication of monthly growth rates (during the period from June 2007 until December 2010).

Accessibility and availability of metadata

All short-term statistics results are freely accessible on the Eurostat website in the the special section dedicated to short-term statistics. Comprehensive, targeted and detailed explanations of methodological issues (metadata) are also made available in various [STS publications](#) (Statistics in focus, Quarterly Panorama of European business statistics) and directly on the [Eurostat website](#) . The database STS sources provides detailed discussions of statistical processes, legal questions, confidentiality rules, data quality and description of national data collection methods. For a number of key indicators additional detailed methodological explanations are also available ([PEEs in focus](#)) .

Short-term business statistics - revisions

Revisions are defined as "any change in a value of a statistic released to the public".

This article provides an overview of revisions and revision policy of [short-term business statistics](#) (STS). The first section presents the main reasons for revisions. The second section describes how the [European statistical system \(ESS\)](#) guidelines on revision policy have been implemented in short-term business statistics. Historical data on the revisions of short-term business statistics are presented in the third section. The article also provides some general conclusions on the quality of STS indicators revealed by the revision analysis.

Reasons for revising short-term business statistics

Routine revisions of short-term business statistics are necessary because of late incoming data, seasonal adjustment or regular benchmarking.

Methodological changes and changes of the reference and base year introduce **main revisions** that may be large in size but take place less frequently and regularly than routine revisions.

Correction of errors may take place at any moment.

- **Late data**

Short-term business statistics publish monthly and quarterly indicators within one to three months after the end of the reference period. To meet these deadlines STS requires early estimations which may have to be revised later when more complete data becomes available. Late data arrival can occur at least at two different levels.

1. Some respondents of statistical surveys in the [Member States](#) send their questionnaires after the national deadlines and the statistical authorities need to estimate the missing data when sending national data to [Eurostat](#). Later, the estimated values are replaced by the more complete data that are re-transmitted to Eurostat.
2. Eurostat often releases its first estimates at the time when some Member States' data are still missing. In short-term business statistics, small countries have often 15 days more time to prepare their national contributions. Later, when all countries have sent their data and some have even revised their first estimates, Eurostat revises the European aggregates.

- **Seasonal adjustment**

Short-term statistics are adjusted for [seasonal effects](#) in order to allow comparing month-on-month or quarter-on-quarter changes whenever indicators are subject to seasonal variation. (For example retail sales in December are always higher than in November because of Christmas shopping. To compare December sales with those of November, the regular impact of Christmas has to be removed from the data.)

The estimation of seasonal effects requires long time series. The mathematical models used to identify seasonal effects work in a way that a new observation can change the seasonal factors applied to the whole time series. Consequently, when the new seasonal factors are applied to the older data, the whole time series may need to be revised. Additionally, an annual (or more frequent) overhaul of seasonal adjustment models is needed to maintain the quality of the models. When models are changed, the adjusted time series are also revised.

- **Benchmarking**

Benchmarking (also called data confrontation or consolidation) is defined as the adjustment of (generally) higher frequency data to take account of more complete lower frequency results, which become available only later. Short-term statistics can be confronted with [structural business statistics](#), labour statistics or [national accounts](#)

. Structural business statistics are also used as the basis for the weights of economic activities within the Member States and for the weights of the countries when compiling the European aggregates of short-term business statistics. They are released more than a year after the end of the reference year, and this has an impact on the updates of weights of the short-term statistics. Furthermore, several countries use quarterly national accounts, for example in estimating the labour productivity that is used for compiling monthly production in construction on the basis of hours worked.

- **Methodological changes**

Methodological changes, including changes of definitions and classifications, are a trigger for major revisions. They cause statistics to be redefined so that the results for the old and the new time series are different, if they are even comparable at all. In the latter case, the users need to be informed about the break in series. Short-term business statistics are classified according to [Statistical classification of economic activities in the European Community \(NACE\)](#) . In 2005, NACE rev. 1.1 was replaced by NACE rev. 2.0 which entailed revisions of those short-term statistics series where the structure of the classification changed.

Currently the replacement of the [Classification of types of construction \(CC\)](#) by NACE and [Classification of products by activity in the European Union \(CPA\)](#) for construction statistics is under discussion. This change would require the recompilation of some construction time series.

- **Changes in base and reference year**

Revisions can also be caused by changes to the base and reference year, which, together with new weighting systems, can alter the paths of time series. The current base and reference year 2005 (2006 for services producer prices) will be replaced by 2010 in the course of 2013. Changing the weighting system will affect also the growth rates of the European aggregates, if the weights of the different countries change considerably. The change of the reference year means that all values of the time series will be divided by the average of the new reference year. This will change the index levels for time series, but it will not have impact on the growth rates.

- **Corrections**

Alterations to the data may also stem from correcting errors. It is not possible to entirely rule out errors during the compilation process in the Member States and in Eurostat. The correction of such errors requires revisions of the published statistical results. The correction of Member States' data leads also to corrections of the European aggregates. Opposite to all other revisions presented above, corrections of errors cannot be planned in advance, but it is possible to inform the users on how errors are dealt with. Significant errors need to be corrected as soon as possible.

Indicator	N	Mean revision			Mean absolute revision			Range		
		t+15d	t+1M	Latest	t+15d	t+1M	Latest	t+15d	t+1M	Latest
Industrial production volume	37	0.1	0.2	0.2	0.2	0.3	0.4	1.6	2.5	3.5
Industrial producer prices (dom.)	37	0.1	0.1	0.2	0.2	0.3	0.4	2.1	5.2	3.7
Industrial import prices (extra-EU)	19	-0.5	-0.3	-1.0	0.7	0.9	1.1	3.0	4.0	3.0
Production volume in construction	37	0.1	0.3	2.3	0.5	0.9	2.5	4.2	4.2	8.0
Retail trade sales volume	37	0.1	0.2	0.3	0.1	0.5	0.5	1.0	2.1	2.2
Services turnover	11	-0.1	0.1	-0.1	0.2	0.6	0.8	1.1	3.7	4.6
Services producer prices	Not enough data available for analysis because reporting started in 2006.									
Building permits:n° of dwellings	11	0.2	0.2	0.5	0.9	2.0	2.5	7.0	9.3	10.1

Release and revision policy of short-term business statistics

In the past all STS data, including the [EU](#) and [euro area](#) aggregates, were revised whenever additional information from national statistical authorities became available. This procedure resulted in almost daily - although usually small - revisions since Member States sent their data on different days to Eurostat. In February 2012 the European Statistical System Committee (ESSC) approved guidelines on how to deal with the various types of revisions for the [Principal European economic indicators \(PEEIs\)](#) , see below.

For short-term business statistics, the following changes were implemented as of October 2012:

- European aggregates are generally released and revised only once per month. This new policy is applied for all Principal European economic indicators (PEEIs), for the industrial turnover indicator and for the retail trade turnover indicator.
- Presently continuous revisions are still applied for all STS labour input indicators (numbers of persons employed, hours worked, gross wages and salaries) and for construction costs and construction prices.

- National data are revised whenever new information becomes available.

The [calendar with the STS release dates](#) is published on the Eurostat website. For indicators subject to a [monthly news release](#), the European aggregates are revised on the same dates.

For other STS [PEEIs](#), industrial turnover and retail trade turnover, the release and revision dates are identical and lie within a few working days after the end of the deadline for new data transmissions from the Member States. Hence data releases and revisions always take place in the beginning of each month.

The new revision policy concerns only routine revisions. Detected errors in national data or in European aggregates are corrected immediately and an error report is released.

Users will be informed about the forthcoming major revisions (e.g. due to methodological changes) in news releases and on Eurostat's website before the event takes place.

Revisions of STS PEEIs - Main statistical findings

In order to monitor the economic and financial development of the Euro area so-called Principal European economic indicators (PEEIs) have been selected. Eight of these 22 indicators are provided by STS:

- [industrial production](#) (volume)
- domestic industrial producer prices
- [industrial import prices](#)
- [production in construction](#) (volume)
- volume of sales in retail trade
- services turnover
- [services producer prices](#)
- [building permits](#) indicators (number of dwellings and useful floor area).

In this section, the following characteristics related to revisions are described for the above indicators (except for services producer prices):

- mean revision
- mean absolute revision
- range (difference between the biggest positive and smallest negative revision)
- revision tracks plotting the path of individual observations after their first release.

Mean revisions should be zero or close to zero. This means that upward and downward revisions cancel each other out and that there is no bias, i.e. that early releases are not systematically higher or lower than later releases.

Mean absolute revisions should be small in comparison with the revised data (e.g. an index or a growth rate). High mean absolute revisions indicate poor accuracy of early releases - even if mean revisions are small and there is no tendency to over or underestimate.

The **range of revisions** represents the difference between the largest and the smallest revisions of different observations.

The following revision analyses are based on index levels since spring 2009, i.e. after the implementation of the NACE rev. 2.0 classification. The figures show the most recent developments, starting from the beginning of 2012 for the monthly data and from the beginning of 2011 for the quarterly. In the figures, each line

shows the development of an individual observation after its first release. An observation is the value of the index in a reference period.

Table 1 reveals bias and volatility of some short-term statistics PEEIs. In the following graphs, the revisions tracks will be used to explain the results of Table 1.

The index of **industrial production** shows some variations after the first release of the data (Figure 1). After the change of the seasonal adjustment method from direct to geographically indirect in March 2012, the revisions of the **EU-27** aggregates have become quite moderate.

Compared to industrial production volume, **domestic industrial producer prices** (Figure 2) show very smooth revision tracks. The initial releases are generally not revised at all. The only exception was a short period in 2009 when the NACE rev. 2.0 was still being implemented at the same time as the new base year 2005.

The big revisions of **extra-EU industrial import prices** (Table 1) can be explained by the fact that Italy started providing this indicator only in December 2011. With its first data delivery, time series going back to 2005 were transmitted. As one of the big euro area countries, Italy has high weight in the **EA-17** aggregates. Consequently, the euro area aggregates were revised systematically downwards for the whole period. Otherwise industrial import prices show generally a stable development after the early revisions following the first release (Figure 3).

In the case of the index of **production in construction (volume)** (Figure 4), there was a systematic increase of all index values in March 2012. This was a result of the change in the aggregation practice that took place at the same time as the change of the seasonal adjustment method: the monthly estimates based on the smaller countries' quarterly data were removed from the total and the monthly index is currently calculated on the basis of the true monthly data only. For this reason, the +2.3 index point change only appears in Table 1 when comparing the first and the latest values.

Volatility was identified as the major deficiency of the index of production in construction (volume) in the EFC's status report of 2008. Eurostat organised a task force in 2010-2011 that issued a report with recommendations aiming at improving the quality of IPC (Guidelines for compiling the monthly index of production in construction). The compilation of the index of production in construction was generally identified as a challenging task. Several countries have started the implementation of the guidelines in their production systems, but the results will not be immediately visible.

Compared to the volume measures of production in industry and construction, the **volume of sales in retail sales** appears to behave very well (Figure 5). Some revisions can be observed in the months following the initial release but afterwards the values seem to stabilise. The range of revisions is the smallest of all STS PEEIs (Table 1).

Services turnover (excluding turnover in retail trade) does not show significant bias, but there appear to be two level shifts of the series in the middle and at the end of 2011 (Figure 6).

The delay of the information from **building permits** authorities to statistical authorities in several Member States is the main reason for the erratic behaviour of the building permits indicators (Figures 7a and 7b). Some reporting countries used to report building permits, in particular in terms of useful floor area, on the basis of incomplete administrative data. Later, when all administrative records were available, the data were revised upwards. In Table 1 this appears as positive bias close to 2 index points. Both indices on building permits used to be very volatile in the first months after the data release. Building permits are based on administrative data in all Member States and they are most often collected by municipalities or regional authorities granting the permits. Eurostat is currently looking for ways to improve the quality of the building permits indicators in cooperation with the Member States.

Conclusion

Outside the major revisions, the short-term statistics price indicators are generally rather stable after the first months following the initial release. However, but volume indices of production in industry and construction and the building permits indicators show some volatility - even long after their first release.

When big countries revise their data, the European aggregates are also revised and this can be observed in the revision tracks of the European main aggregates. The major methodological changes, for example the change of classifications, the base year or the seasonal adjustment method understandably introduce revisions to the entire length of the concerned time series.

Short-term business statistics - seasonal adjustment methods

As of 1 March 2012 Eurostat changed the method for seasonal adjustment of European Union (EU) short-term statistics (STS) data from a direct to an indirect approach. This article describes and compares the two different approaches and outlines their respective advantages and possible shortcomings. It also provides a short overview about the various types of data adjustments used in short-term statistics and a brief explanation of seasonal adjustment techniques.

Note that in this article the terms "direct" and "indirect" refer to the *geographical* dimension of the STS data, i.e. the way in which national data are aggregated to European data. In another context direct and indirect methods might be used, for instance, to aggregate data from sub-industry level to industry level etc.

Adjustment of short-term statistics data

Eurostat publishes national and European short-term statistics indicators of the following types:

- gross data (g), i.e. data without any adjustment;
- **working-day adjusted** data (wa) in which calendar effects (leap years, public holidays, different number of Saturdays and Sundays between months etc.) have been removed;

Gross data = residual + trend + seasonal component + calendar component

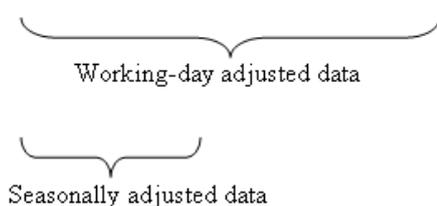

Figure 1: Components of an STS time series

- seasonally adjusted data (sa) in which not only calendar effects have been removed but also seasonal effects (e.g. the effect of summer holidays on production or Christmas shopping on retail turnover);
- **trend** data (t).

The mathematical models for the various adjustments are rather complex and cannot be described here (well-known seasonal adjustment programmes are for example TRAMO-SEATS or Census-X12 ARIMA). Generally it can be said that one important aspect for the quality of the adjustment is that the residual component of the gross data is rather small, or in other words that most of the development of a **time series** is either explained by a trend, by seasonal effects or by calendar effects.

STS requirements

Generally, the **STS Regulation** does not oblige **Member States** to transmit seasonally adjusted data to Eurostat but only requires working-day adjusted data.

With few exceptions, seasonally adjusted data are calculated by Eurostat for all countries and for all data series. However, in a number of cases Member States calculate their own seasonally adjusted data and transmit them on a voluntary basis to Eurostat. Where this happens, Eurostat publishes the national results in order to

avoid discrepancies between European published data and nationally published data.

To calculate European aggregates from the national data several approaches are possible. In this article the two cases used by Eurostat are discussed: a direct approach (used until March 2012) and an indirect approach (used as of March 2012).

Indirect approach and direct approach of seasonal adjustment

Indirect approach (as of March 2012)

In the indirect approach seasonally adjusted European aggregates are calculated as follows:

- where national seasonally adjusted time series are available (see above), these are used;
- where seasonally adjusted series are not available they are calculated by Eurostat;
- these seasonally adjusted series for the EU-Member States (or the Euro area) are then weighted and combined to yield an aggregate European time series.

The approach is called indirect because the seasonally adjusted European aggregate is not seasonally adjusted itself but is based on national inputs which have been adjusted before the aggregation.

Direct approach (until March 2012)

In the direct approach the national time series (either working-day adjusted or gross data) were first weighted and aggregated and the seasonal adjustment is then performed directly on the European aggregate.

Table 1: Industrial Production Index – Total Industry, July 2011

	Working-day adjusted index	Weights (%)	Index * Weight	Different seasonal adjustments	Seasonally adjusted index	Index * Weight
Germany	114.6	44.5	51.0	—SA _{DE} →	115.4	51.4
Spain	89.5	13.0	11.6	—SA _{ES} →	83.8	10.9
France	94.3	20.6	19.4	—SA _{FR} →	95.2	19.6
Italy	98.9	21.9	21.7	—SA _{IT} →	89.3	19.6
Indirect			103.7	— / →		∑ = 101.5
Direct			103.7	—SA _{aggregate} →		99.8

Table 1: Example - direct and indirect seasonal adjustment

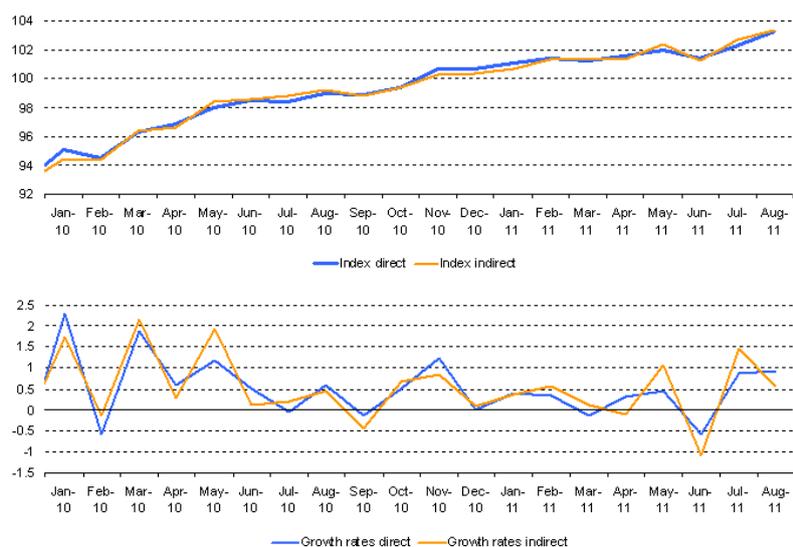

Figure 2: EU-27 Industrial production, index and growth rate, differences between direct and indirect seasonal adjustment

Table 1 illustrates the two methods with a simplified example for the industrial production index in July 2011. According to the indirect method the value of the index is 101.5 which is the weighted sum of the independently seasonally adjusted values for Germany, Spain, France and Italy. According to the direct method the value for the index is 99.8 which is calculated from the working-day adjusted weighted index for the four countries with a model that is specific for the aggregate of these four countries.

Benefits and shortcomings of the approaches

The indirect approach has several advantages.

- (Seasonally adjusted) European averages are fully consistent with national seasonally adjusted data. Where e.g. seasonally adjusted national data and European aggregates are published in the same tables, users can check the consistency by weighting and adding up the data for the Member States. This is not the case with the direct approach. Consistent national and European data entail greater credibility of the results.
- Generally Member States are obliged to transmit working-day adjusted data to Eurostat (see STS requirements). The indirect adjustment approach used for the calculation of European working-day adjusted aggregates. Using the same approaches for working-day adjustment and seasonal adjustment thus creates greater consistency.
- If new European aggregates have to be calculated (because the composition of the European Union or the [euro area](#) changes, for instance) it is not necessary to define new seasonal adjustment specifications for the new aggregate, only a new [weighting](#) scheme would have to be developed.
- National statistical institutes have more detailed information available which they can employ for the calculation of their seasonal adjustment. Using these data as input can be expected to lead to higher quality in the European aggregates than using one single European adjustment method on the aggregated input data.
- One advantage of a direct approach is that for each data series the optimal adjustment method can be found which takes into account specific aspects of this series. In that way the residual component of the data series can be minimised and most of the development of the series can be explained by trend, seasonal effects of calendar effects (see above).
- A direct approach can also have advantages when the various methods for seasonal adjustment that are used by the Member States are very diverse. In such a case the indirect approach would add up national

results which are not comparable due to different methods for seasonal adjustment. The development of the European aggregates could then be difficult to interpret.

Quantitative comparison

Which method – direct or indirect – is better cannot be decided a priori but depends on the circumstances (see above). For most European STS-indicators the quantitative differences between the two approaches are not very big.

Figure 2 shows the recent development of the [EU-27 industrial production index](#) calculated with the direct and the indirect method. For the indices differences are marginal. For the respective growth rates however differences can be observed. The advantage of the indirect method of guaranteeing consistency between European aggregates and national results is therefore of particular importance for the growth rates.

Construction cost index overview

Data from November 2012, most recent data: Further Eurostat information, main tables and database .

The construction costs index (CCI) (sometimes also referred to as “construction factor price index” or a “construction input price index”) is a [European Union \(EU\) business cycle](#) indicator showing the trend in the costs incurred by contractors in the construction of [buildings](#) . The CCI presents the total costs for new buildings. In addition, an index for material costs and an index for labour costs are available. Material and labour costs represent the most important cost components for construction.

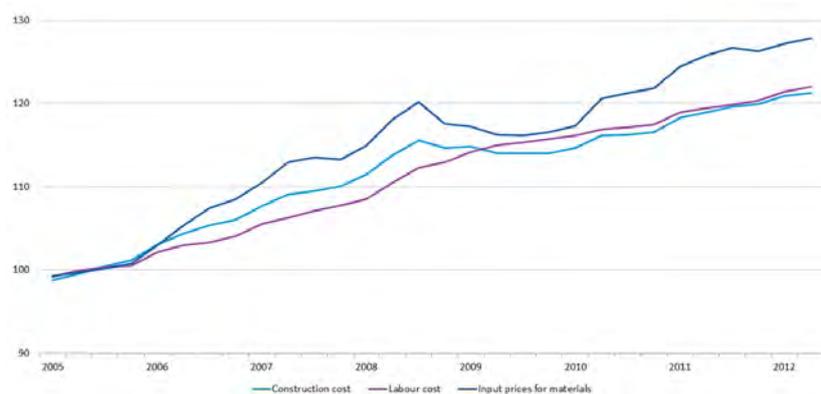

Figure 1: EU-27 quarterly construction cost index and its components for new residential buildings, quarterly gross data (2005=100), Source: Eurostat (sts_copi_m)

Table 1: Annual growth rates, construction cost indices for new residential buildings, gross data (2005=100), Source: Eurostat (sts_copi_a)

Between 2005 and mid-2008 construction costs (for [residential buildings](#)) increased relatively steadily in the [EU-27](#) with an annual rate of around 4.4% (Figure 1). In the third quarter of 2008 the index began to fall and reached its lowest level of 114.0 one year later. In the last quarter of 2009 the index started to increase again. Less than one year later it regained the level it had displayed before the crisis. The development of the construction cost index was mainly influenced by the material cost component, while the labour cost component continued to grow even during the crisis - although at a somewhat slower pace than before.

Table 1 provides the annual growth rates for the EU-27 and its Member States for the period between 2005 and 2011. With few exceptions the EU countries display a development that is broadly similar to the one that can be found for the EU [aggregate](#) . Differences can be found in the timing and the size of the decrease of the cost index. The construction cost index for residential buildings started to fall first in Ireland (but note that in Ireland the cost index is approximated by a price index, see below), in the other countries this development occurred only several months later. The reductions of the cost index were strongest in Ireland and in the [Baltic States](#) . In a number of countries the rates of change in 2008 and 2009 remained positive although much lower than in the first half of the period under observation.

Data sources and availability

Data collected by Member States are transmitted to [Eurostat](#) as an index, with the year 2005 as base year. The [Short-term statistics Regulation \(STS-R\) 1165/98](#) calls for quarterly indices on construction costs for new residential buildings, excluding residences for communities. Data are revised when additional information from national statistical authorities becomes available. In general, no special surveys are undertaken in order to calculate the construction cost index since it is possible to use other indices that are already available from different sources.

The weighting for aggregating this index between Member States is generally turnover in building construction and is derived from information obtained from [structural business statistics](#) or other statistics.

Countries that do not have data on construction cost may use construction producer prices (construction output prices) as an approximation. Countries following this praxis are Belgium, Ireland, Luxembourg, Poland, Slovakia and the United Kingdom. For some countries (the Czech Republic, Germany, Greece, the Netherlands and Austria) both indicators, construction costs and construction producer prices (construction output prices) are available. In general both indicator display almost the same developments.

Labour	Collective agreements, Labour cost survey
Equipment	Producer Price Index for machinery
Energy	Producer Price Index, Wholesale price index

Table 2: Sources for the construction cost index

The CCI provides important additional aspects to the information provided by other construction data. The CCI measures developments from the points of views of the building contractors. It reflects the prices that they have to pay for the input factors in the construction process (see A in Figure 2). The cost index therefore has to be distinguished from the [producer price index](#) for construction (also called output price index) which are seen from the point of view of the contractors' clients. The producer price index/output price index (see B) shows the development of prices paid by the client to the contractor. These two indices can be distinguished from the "selling price index" (item C) which measures changes in the prices paid by the final owner of the output to the client. It includes the price of the land, architect's fees and client's margins.

The CCI measures the relationship between the costs, at constant technology and constant input mix, that are associated with the implementation of a fixed amount of construction work. This type of index is different from a producer price index, which measures movements in prices charged to clients of construction work. This is especially true when the price index is calculated from tender prices, which can vary from time to time and place to place depending on the state of competition and market conditions. Producer price indices include

changes both in productivity and in the contractor's margins. This corresponds to item B in Figure 2.

The CCI is made up of aggregated price indices for materials, labour costs and other types of costs. The aggregation takes into account the relative [weights](#) for the different cost components. The component costs index (material costs and labour costs) shows the price developments of production factors used in the construction industry. Plant and equipment, transport, energy and other costs are also components of the construction costs. Architect's fees are not part of the construction costs. The material costs index is generally calculated using materials prices and should be based on actual prices rather than list prices. They should also be based on a sample of products and suppliers. Prices are exclusive of [VAT](#). The labour cost index for the construction sector should cover wages and salaries and social security charges for all persons employed in the construction sector. Social security charges include statutory [social contributions](#) payable by the employer as well as collectively agreed, contractual and voluntary social contributions payable by the employer and also [imputed social contributions](#) (social benefits paid directly by the employer). It is assumed that neither the construction method nor the building organisation have undergone any change, and consequently the calculations take no account of factors such as [productivity](#) improvements, more efficient utilisation of materials, etc. which may influence cost trends. Changes in the profit margins, which also affect a producer price index, have not been taken into account either. The coverage of this indicator is limited only by the [Classification of types of construction \(CC\)](#).

Construction permit index overview

Data from July 2012, most recent data: Further Eurostat information, main tables and database .

The indices for building permits are [business cycle](#) indicators providing an indication of the future activity of the [European Union \(EU\)](#) construction sector.

[Short-term statistics](#) provide two types of indices for building permits. The so-called "dwelling index" simply reflects the evolution of the number of [dwellings](#) . A second indicator, the "floor area index" reflects the development of the useful floor area for which the building permits are issued (where the useful floor area cannot be ascertained, an alternative size measure may be used).

The building permits index for the number of permits covers one-dwelling [residential buildings](#) and residential buildings with two or more dwellings but not residential buildings for communities (e.g. residences for the elderly) (see [Classification of types of construction \(CC\)](#)). The building permits index of useful floor area covers all types of residential buildings and also other buildings, for example hotels, shops, warehouses, industrial buildings, schools and hospitals.

Table 1: Construction permits, number and floor area, annual rates of change, gross data, 2005-2011, Source: Eurostat (sts_cobpgr_a)

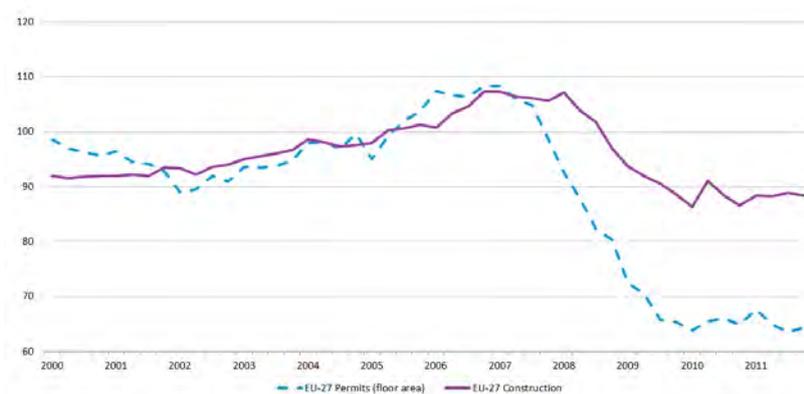

Figure 2: Construction permits indicators and construction output for the EU-27 (2005=100), Source: Eurostat (sts_cobp_q) and (sts_copr_q)

Main statistical findings

For the [EU-27](#) the dwelling indices peaked in the first quarter of 2006 and then began a relatively continuous downturn which lasted 3 years. In 2009 the bottom of the cycle appears to have been reached. For the last 3 years the index remained rather stable at a level which was only half of the pre-crisis peak. Figure 1 shows that both indicators for residential buildings (excluding buildings for communities), i.e. the indicator for the number of dwellings and the indicator for the floor area develop in a very similar fashion. Figure 1 also presents the area-index for [non-residential buildings](#). This indicator reacts with a certain delay compared with the indicators for residential buildings.

The development of building permits is rather heterogeneous at the level of the individual Member States. In several countries the indices for the number of buildings or the useful floor dropped by half or even more during individual years while in some countries even two-digit growth rates were recorded for the same periods. Generally, the negative development between 2005 and 2011 was most pronounced in Ireland, Spain and Portugal. In Austria, Luxembourg and Poland the development between 2005 and 2011 was even positive although all countries recorded negative rates of change in certain years.

Data sources, aggregation and availability

Information on building permits is generally collected from the authorities who issue the permits (often municipalities). As the collection of information is exhaustive, questions of sample sizes, weighting etc. do not apply. The mandatory [reference period](#) under the [Short-term statistics Regulation 1165/98](#) is at least one quarter. Several Member States actually provide data on a monthly basis. The data are generally available 3 months after the end of the reference period.

Context

A building permit is granted by public authorities in response to an application and based on a specific building plan. It is the final administrative authorisation to start work on a concrete building project and one of the last steps before actual construction work starts. Works for which no permit is required will generally be rather limited. Therefore the development of the indicator of building permits is rather close to the development of actual work. However the leading indicator quality of the permits has to be interpreted with some care as there is no immediate link between the two. In none of the countries covered by the short-term statistics regulation does the permit imply an obligation to start the construction. Therefore some permits might not be used by the builders and the index for building permits might overestimate future building activities. Moreover, the time between the issue of the permit and the start of the construction work can vary depending e.g. on the type of construction, on the business cycle or the country. Even if there was a regular delay between the permit and the start of the construction work the statistical connection between development of permits and development of construction output could still vary depending on how fast or slow the construction work proceeds.

The financial crisis of 2007 – 2010 which was triggered by the downturn of the US housing market and which resulted in substantial losses of construction output highlighted the need for more information on the housing market. The building permit indices were therefore integrated into the list of ' [Principal European economic indicators](#) ' or 'PEEI' (together with residential property prices and house sales).

Construction producer price index overview

Data from November 2012, most recent data: Further Eurostat information, main tables and database .

The construction producer price index (CPPI) (sometimes also referred to as “construction output price index”) is a [European Union \(EU\) business cycle](#) indicator showing the trend in the prices for new residential [buildings](#) .

The current [Short-term statistics Regulation \(STS-R\) 1165/98](#) calls for quarterly indices on [construction costs](#) for new residential buildings (excluding residences for communities). Countries that do not have data on construction costs may use construction producer prices (construction output prices) as an approximation. Countries following this praxis are Belgium, Ireland, Luxembourg, Poland, Slovakia and the United Kingdom. For some countries (the Czech Republic, Germany, Greece, the Netherlands and Austria) both indicators, construction costs and construction producer prices (construction output prices) are available. In general both indicators (construction costs and construction producer prices) display almost the same developments.

	2005	2006	2007	2008	2009	2010	2011
Belgium	100.00	104.90	109.58	112.30	111.08	111.07	115.43
Czech Republic	99.93	102.88	107.39	112.23	113.07	112.25	111.75
Germany	100.00	101.91	105.91	109.00	109.90	111.01	114.06
Ireland	100.02	109.64	111.51	102.96	92.81	93.32	91.26
Greece	100.01	102.86	105.73	110.20	109.98	110.33	110.23
Luxembourg	100.01	102.86	105.89	109.24	110.81	111.66	114.54
Netherlands	99.99	100.08	104.74	110.78	109.92	104.53	103.82
Austria	100.00	102.86	107.21	112.26	114.85	116.88	120.18

United Kingdom	100.04	104.78	108.41	114.61	115.52	115.73	117.33

Table 1: Annual construction producer price indices for new residential buildings, gross data (2005=100), Source: Eurostat (sts_copi_a)

Main statistical findings

Between 2005 and 2008 construction producer prices (for [residential buildings](#)) increased in steadily all ten countries for which these data are available. After 2008 construction producer prices remained relatively stable in most countries for two years and only recently started to increase . In Austria prices showed a steady increase during the whole period under observation. In the Netherlands and Ireland prices dropped significantly (Table 1).

Data sources and availability

Data on construction producer prices are not a mandatory requirement under the current [Short-term statistics Regulation](#) but may be used as an approximation for the construction costs data. Data collected by Member States are transmitted to [Eurostat](#) as an index, with the year 2005 as base year.

Construction production (volume) index overview

Data from October 2012: Further Eurostat information, main tables and database .

The production index for construction is a [business cycle](#) indicator which measures monthly changes in the price adjusted output of construction. The construction production index corresponds to the [industrial production index](#) but covers (parts of) [NACE](#) section F.

Table 1: Annual rates of change for buildings and civil engineering, working-day adjusted, 2005-2010, Source: Eurostat (sts_coprgr_a)

Since around 1998 construction output in Europe had increased rather steadily; but with the economic and financial crisis in 2007 output began to decline quite dramatically. Within 3 years the level of total construction in the EU-27 fell to the level that it had reached in 1999, i.e. 8 years before the crisis (Figure 1). Only in 2011 construction activities stabilised and in recent months even increased slightly in the EU-27.

The development of overall construction was very similar for the EU-27 and the Euro area (EA-17) (Figure 1). However there are noticeable differences between the development of the construction of buildings (residential and non-residential) which accounts for around 78% of total construction and the development of the construction of civil engineering works (e.g. railways, roads, bridges, airport runways, dams) which accounts for around 22% of total construction (Figure 2).

The crisis in the building sector hit all EU-27 countries albeit to a different extent. All countries experienced a decline in building production ranging from an extreme reduction of -49.5% in Lithuania in 2009 to almost stable activity levels in Germany. In several countries (e.g. the Baltic countries, Spain, France, Hungary) growth rates had already begun to move downwards around the year 2005 while in several other countries the drop in building activities happened in a more sudden way and was shorter. (Table 1).

Data sources, aggregation and availability

The obligation to transmit construction production data to Eurostat was already foreseen in the first STS Regulation 1165/1998.

Like the industrial production index the construction production index is intended to reflect the monthly volume value added of the construction sector. This variable is however not directly observable and must therefore be approximated by other measures such as deflated gross production or input of labour and raw materials.

Eurostat publishes, on a monthly basis, the construction production index for the EU, for the euro area and the Member States; data are also collected for the Former Yugoslav Republic of Macedonia (FYROM) and Turkey. Data are presented in working-day adjusted and in seasonally adjusted form, trend data and rates of change are also available. Currently the indices for construction production are calculated with 2005 as the base year (=100).

Context

Currently the EU-27 construction sector accounts for more than 6% of (gross) value added. Although the relative share of construction in Europe's economic activity has declined a little over recent years construction is still of high importance for our economies. The indices for the development of construction output is therefore an important tool for the European Central Bank and the National Central Banks for monitoring

and analysing economic developments. Production in construction is one of the so-called ' [Principal European Economic Indicators \(PEEI\)](#) ' which are used to monitor and steer economic policy in the EU and in the euro area.

Industrial import price index overview

Data from August 2012: Further Eurostat information, main tables and database .

The **industrial import price index** (abbreviated as IMPR or sometimes MPI) is a **business cycle** indicator which measures monthly changes of prices of products which are imported by domestic **enterprises** from other countries.

According to the **short-term business statistics regulation** only countries in the **euro area** (**EA-17**) are obliged to transmit import prices to **Eurostat** . However several non euro-area countries in the **European Union (EU)** and even some **EFTA** countries provide this information as well.

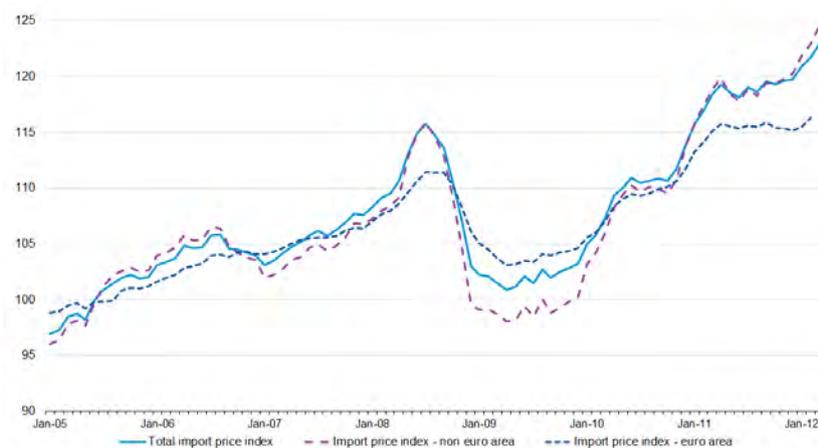

Figure 1: EA-17 industrial import prices for total industry, euro and non-euro-area (gross), 2005-2012, Source: Eurostat (sts_inpi_m)

The indices for import prices are calculated with a distinction between imports coming from within or outside of the euro area.

Table 2: EA-17 Industrial import price index, annual rates of change, total industry, main industrial groupings and economic activities, 2005-2011, Source: Eurostat (sts_inpigr_a)

Between January 2005 and July 2008 (pre-crisis peak) import prices for total industry increased at an average rate of 0.42% per month (5.08% per year). In the following nine months until April 2009 import prices dropped at a pace of around 1.51% every month to the level of three and a half years earlier. Since mid-2009 the price level has increased again with an average monthly rate of 0.53% and is now a good 7 points higher than its previous peak. The development for prices in the euro area and non-euro area were rather similar although the volatility within the euro zone was somewhat weaker than for the prices from other currency areas (Figure 1).

For the different [main industrial groupings](#) price developments were relatively heterogeneous. Intermediate goods and non-durable consumer goods show a similar pattern as total industry (of which they make up more than 50%), i.e. an increase between 2005 and the second half of 2008, a prolonged fall until around mid-2009, followed by a relatively dynamic increase which resulted in index levels several points higher than before the crisis.

Prices for capital goods and durable-consumer goods had shown a declining development since 2005/2006. This development changed however in the first half of 2008. Since then import prices for capital goods have, despite some up and down movements, shown a rather stable trend. Import prices for durable consumer goods have even increased somewhat and regained the level of 2006.

Import prices for energy products (which constitute almost 15% of the total euro area index) rose steeply (3% per month on average) between January 2007 and July 2008. Then they fell even more quickly for about half a year (average of almost -9% per month) and have since then increased again at a rapid pace (Figure 2).

In all countries for which data since 2005 are available total import prices show basically the same up-and-down-pattern. Positive rates of around 4% or more in 2006 followed by lower but still positive rates in 2007 and again relatively high rates in 2008. For 2009 all countries recorded negative rates of change (corresponding with the steep fall of the index in the second half of 2008 and early 2009) and again relatively high positive rates in 2010 and 2011 (Table 1).

Data sources and availability

The obligation to transmit import price data to Eurostat was introduced in 2005 by [Regulation 1158/2005](#) of 6 July 2005.

The import price indices cover most mining activities and a large number of manufactured products at the 2-digit level of the [NACE Rev. 2](#). The index is calculated on the basis of the [Statistical classification of products by activity \(CPA\)](#). Some product groups are however excluded (such as nuclear products, weapons, ships and aircrafts, printing and some repair services, see Table 2).

Import prices in short-term statistics are defined as follows, they:

- include cost, insurance and freight at the national border of the importing country, but not duties or import taxes;
- are actual transaction prices (not list prices) including e.g. discounts;
- are measured in the currency of the importing country. Transactions in other currencies have to be converted (this implies that the import price index is affected by [exchange rate](#) fluctuations);
- must take into account all price determining qualities of the imported products (e.g. service and guarantee conditions, included transport costs etc.);
- are recorded when ownership is transferred and the index should reflect the average prices during the reference period (month).

Currently the indices for industrial import prices are calculated with 2005 as the base year (=100).

Context

The industrial import prices index shows the development of prices of goods imported by enterprises which are used as intermediate products in their production process, as capital goods or as goods to be resold to consumers. The development of the index is used to forecast the development of other prices notably for domestic goods. The index is an important tool for the [European Central Bank](#) and the national central banks for monitoring and analysing inflationary developments. Industrial import prices are part of the so-called ' [Principal European Economic Indicators \(PEEI\)](#) ' which are used to monitor and steer economic and monetary policies in the EU and in the euro area.

Industrial producer price index overview

Data from October 2012, most recent data: Further Eurostat information, main tables and database .

This article provides a general overview of the (industrial) [producer price index \(PPI\)](#) , sometimes also called output price index, as it is calculated and used at the level of the [European Union \(EU\)](#) and its Member States.

The producer price index measures the gross monthly change in the trading price of products. (There is another index for services, the so-called [services producer price index \(SPPI\)](#) .) There are two sub-indices for the industrial producer price index, one for the domestic and one for the non-domestic market. When combined, the sub-indices for these two markets give the change in the PPI for a given product. The PPI is a producer price index, it measures price changes from the point of view of the producer/ manufacturers of a product. In this it differs from consumer price indices which measure the prices from the point of view of consumers/buyers.

The index reflects basic prices, which excludes [VAT](#) and similar deductible taxes directly linked to [turnover](#) , whereas any subsidies on products received by the producer should be added. In order to show the true development of price movements, actual transaction price are collected not list prices. For output prices on the non-domestic market, the price are calculated at national frontiers, FOB (free on board); this means that the seller pays for transportation of the goods to the port of shipment, plus loading costs, and the buyer pays freight, insurance, unloading costs and transportation from the port of destination to his factory. All characteristics that determine the price of the products, including quantity of units sold, transport provided, rebates, service conditions, guarantee conditions and destination, have to be taken into account.

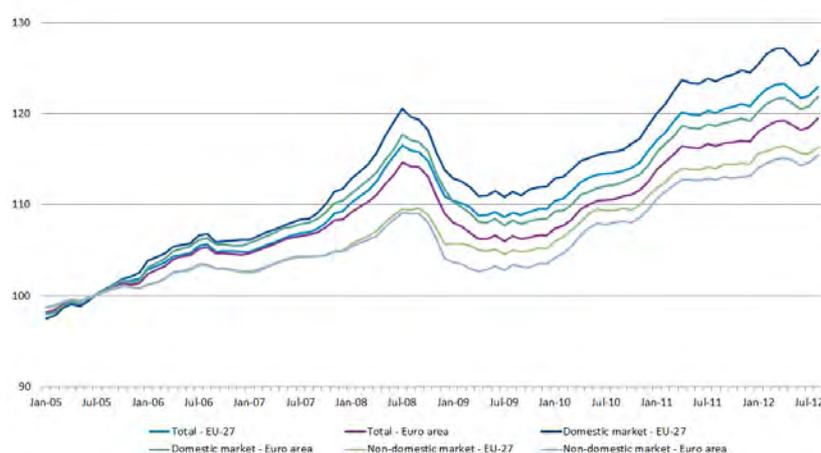

Figure 1: Industrial producer prices indices, total industry (excluding construction), EU-27 and Euro area

Main statistical findings

After a steady increase for several years producer prices peaked in summer 2008 and then dropped significantly for several months as a result of the financial and economic crisis. However, after about one year prices began to increase again and in late 2010/early 2011 regained their former peak level. As Figure 1 illustrates the various sub-indices for the [EU-27](#) , the [euro area](#) and for domestic and non-domestic market all moved in a very similar fashion.

Table 1: Index of total producer prices, total industry (excl. construction), gross data.

Table 1 shows the annual rates of change for the EU-27, the euro area and the individual [Member States](#). While there are some differences in the magnitude of the rates it can be seen that the general pattern of a steady increase until 2008, a quick drop and a new increase since 2009 is shared by almost all countries.

Data sources and availability

Coverage

The data collection at European level results from the [Regulation 1165/98](#) which was adopted in 1998 and amended in 2005 by [Regulation 1185/2005](#). In parallel to the adoption of the legal texts, [Eurostat](#), with the help of Member States, has developed a methodological guide to ensure consistent data collection in all countries.

All Member States are obliged to transmit data at 2-digit level of the [NACE](#) classification (an EU standard classification of economic activities) for:

- Mining and quarrying (Section C);
- Manufacturing (Section D);
- Electricity, gas and water supply (Section E).

The industrial output price index is published monthly. Countries send data to [Eurostat](#) no later than one month and 5 days after the end of the [reference period](#). Eurostat publishes the European price index one month and 5 days after the reference period.

Data collection

The PPI data are based on selling prices reported by establishments of all sizes selected as being representative of the whole population. Regular collection of prices data normally flows from a sample of units and a sample of their products. Data are generally collected using mainly postal questionnaires or by telephone surveys, and increasingly by electronic means. The basic sampling method used varies from one national statistical authority to another (cut-off sampling or sampling proportional to size are applied) and depends on the market that is being studied – i.e. domestic or non-domestic. On the domestic market, the sample of enterprises is normally drawn from the Statistical Business Register. The observation units for the PPI for the non-domestic market are very often selected from external trade data. Samples for the PPI for the non-domestic market are generally much smaller than those for the domestic market.

Weights are based on turnover information from the Structural Business Statistics database or on information coming directly from Member States. Weights and base years are revised every five years. The current

base year is 2005.

Context

PPI data are widely used by both the business community and government, and enable monthly monitoring of prices at different stages of the manufacturing process. There are three major uses of PPIs.

- As an economic indicator – PPIs capture price movements prior to the retail level. Therefore, they may foreshadow subsequent price changes for businesses and consumers. They can be an early indicator of inflationary pressures in the economy. These data are used in formulating fiscal and monetary policies.
- As a [deflator](#) of other economic series – PPIs are used to adjust other economic time series for price changes.
- As the basis for contract price adjustments (escalation) – PPI data are commonly used in escalating purchase and sales contracts. These contracts typically specify amounts of money to be paid at some point in the future. It is often desirable to include an escalation clause that takes account of increases in input prices.

In many countries, there is a big demand for PPIs from the business and trade organisations. As these indices have already been in existence for decades, they are part of economic life for national accountants and businesses. For these uses they need to be maintained by the national statistical institutes at a detailed level. Many medium-sized and small countries calculate detailed PPIs beyond the requirements of the EU Regulation in order to satisfy a national demand.

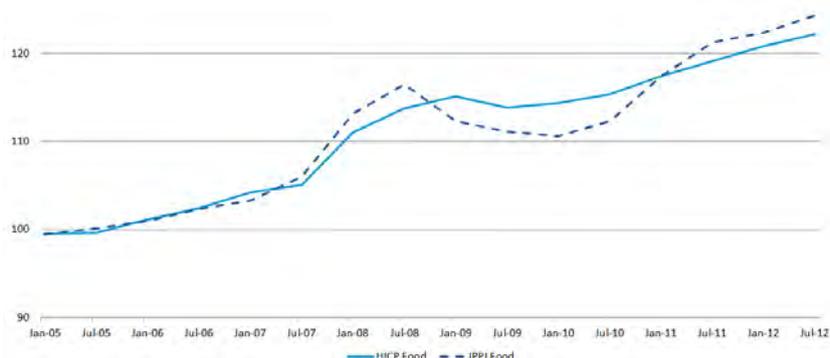

Figure 2: Comparison of producer and consumer price indices for food products (EU-27)

To some extent the direction and magnitude of changes in the PPI for finished goods prefigures a similar change in the [consumer price index \(CPI\)](#) for all items. This relation is however not general. Both the PPI and CPI measure price change over time for a fixed set of goods. A primary use of the PPI is to [deflate](#) revenue streams in order to measure real growth in output. A primary use of the CPI is to adjust income and expenditure streams for changes in the cost of living. The different uses cause various conceptual differences that can be described as follows:

- The definition of prices – The price collected for an item included in the PPIs is the revenue received by its producer. Sales and excise taxes are not included in the price because they do not represent revenue to the producer. The price collected for an item included in the CPI is the expenditure by a consumer for the item. Sales and excise taxes are included in the price because they are necessary expenditures by the consumer for the item.

- The composition of the set of commodities and services – The target set of goods and services included in the PPIs is the entire marketed output of the producers. The set includes both goods and services purchased by other producers as inputs to their operations or as capital investment, and goods and services purchased by consumers either directly from the service producer or indirectly from a retailer. Because the PPI target is the output of the producers, imports are excluded. The target set of items included in the CPI is the set of goods and services purchased for consumption purposes by the households. This set includes imports;

Industrial production (volume) index overview

Data from July 2012: Further Eurostat information, main tables and database .

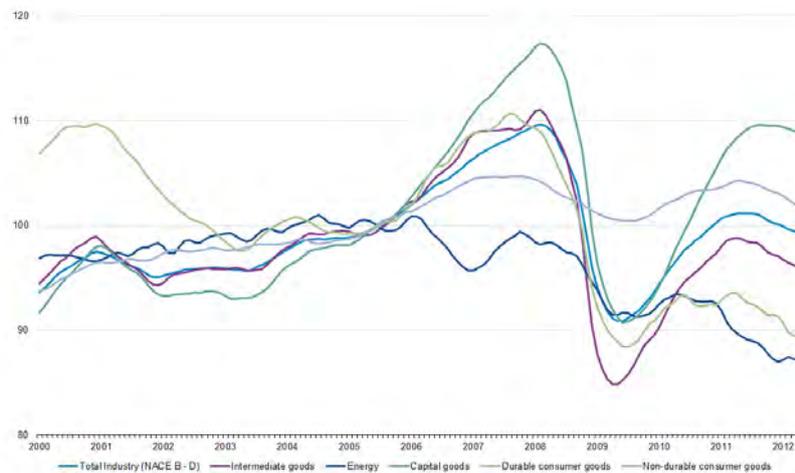

Figure 1: EU-27 Industrial output (trend) for total industry and the main industrial groupings, 2000-2012 (April), Source: Eurostat (sts_inpr_m)

The **industrial production index** (abbreviated IPI and sometimes also called industrial output index or industrial volume index) is a **business cycle** indicator which measures monthly changes in the price-adjusted output of industry. This article takes a look at the industrial production index as it is calculated in the **European Union (EU)** as well as in some **EFTA** and **candidate countries** .

Table 2: Annual rate of change industrial production for the EU and for the Member States 2000-2010, working day adjusted, Source: Eurostat (sts_inprgr_a)

Since mid-2003 industrial output had been on a relatively steady growth path for total industrial production and all [main industrial groupings](#) with the exception of energy (which had already been on a longer-term decline since 2005/2006). Total industrial production reached its highest value in February 2008 and then fell continuously for over a year until in early 2009 it was around 19% below its former peak. Afterwards the indicator steadily increased again and regained over 90% of its pre-crisis value by May 2011. Since then however, industrial production in the EU-27 has been on a slow downward trend (Figure 1).

When distinguishing between main industrial groupings, data show that the production of capital and intermediate goods peaked in early 2008, while for consumer durables the highest index value had already been reached in summer/autumn 2007. With the onset of the economic and financial crisis industrial production fell significantly and rapidly. Within the time span of just over one year the production of capital goods and of intermediate goods was reduced by 23% ([trend](#) figures). The decline in the production of durable consumer goods which had already begun in mid-2007 lasted around two years but was equally strong (-20%). The development of non-durable consumer goods was less dramatic. Between the end of 2007 and mid-2009 the European production in this industrial grouping fell by around 4.1% (Figure 1).

Table 1 shows a breakdown of the general development of the main industrial groupings in more detailed [NACE](#) divisions. The 2009 decline in production was particularly strong for machinery and equipment and for motor vehicles which together account for more than 15% of total industrial production. Considerable negative rates of change were also recorded for electrical equipment, for basic metals and fabricated metal products. The magnitudes of the various rates of change for consumer goods reflect consumers' possibilities and inclinations to adjust their consumption to the new circumstances in the economic crisis. While food production in the EU-27 declined by -0.9% and beverages by -2,3%, the production of wearing apparel was reduced by over 11%, the production of printed and recorded media by more than 7% (Table 1).

The economic crisis did not start in all Member States at exactly the same moment (Table 2). Several countries (Estonia, Greece, Spain, Luxembourg, and Portugal) already recorded negative rates of change above 4% in 2008 but a relatively large number of countries still displayed positive growth rates of industrial production. In 2009 all EU countries experienced a fall in industrial production and the European average rate of decline was around -14%. In 2010 all EU countries with the exception of Greece and Cyprus had returned to positive growth rates. For 2011 the EU-27 as a whole still displayed a positive industrial growth of more than 3%. However, in seven countries industrial production has decreased again.

Data sources and availability

Despite its name the industrial production index is not intended to measure production but should – in theory – reflect the development of [value added](#) in the different branches of industry. This means that the inputs obtained by one branch from another must be deducted from its gross output. In this way double counting of

production is prevented and the degree of vertical integration of branches should not influence the results for the indicator.

In practice, however, it is difficult to collect value-added data on a monthly basis. Most statistical institutes therefore derive monthly production data from other sources including [deflated turnover](#) , physical production data, labour input, intermediate consumption of raw materials and energy etc.

[Eurostat](#) publishes, on a monthly basis, the industrial production index for the EU, for the [euro area](#) and the Member States; data are also collected for Norway, Switzerland, Croatia, Turkey and the former Yugoslav Republic of Macedonia. Data are presented in [working-day adjusted](#) and in [seasonally adjusted](#) form, trend data and rates of change are also available. Currently the indices for industrial production are calculated with 2005 as the base year (=100).

Context

The industrial production index is one of the most important short-term statistics indicator. It is used to identify turning points in the economic development at an early stage and to assess the future development of [GDP](#) . In order to serve this purpose it is available on a monthly basis in a detailed activity breakdown and with a rather short delay (1 month and 10 days). The industrial production index is one of the so-called ' [Principal European economic indicators \(PEEI\)](#) ' which are used to monitor and steer economic and monetary policies in the EU and in the euro area.

Industrial turnover index overview

Data from March 2012, most recent data: Further Eurostat information, main tables and database .

This article provides an overview of the development of the industrial turnover indicator in the [European Union \(EU\)](#) , the [euro area](#) and the [European Member states](#) over recent years and describes how it is compiled. The index of industrial turnover is a [business cycle](#) indicator which measures the monthly development of turnover in the European industry.

The data presented in this article are taken from European [short-term statistics \(STS\)](#) which are collected under the [short-term statistics regulation](#) . Industry turnover as presented in this article covers turnover in mining and quarrying and in manufacturing ([NACE Rev. 2](#) sections B and C).

Table 1: Turnover in industry, annual rates of changeSource: Eurostat (sts_intvgr_a)

Figure 2: Turnover and production in industry, EU-27, 2000-2011 Source: Eurostat (sts_intv_m) and (sts_inpr_m)

Between 2001 and 2003 industrial turnover in the EU-27 remained rather stable but afterwards increased steadily until April 2008 when a rapid decline set in (see Figure 1). Within a period of just over one year the index for European industrial turnover fell to a level which it had had four years before the peak in 2008. Since then a steady increase has set in and the recent turnover values have almost regained the pre-crisis level.

Industrial turnover data published by Eurostat distinguish between domestic turnover, i.e. turnover generated with sales to units in the same country and non domestic turnover for sales from a business in one country to someone in another country. (The non domestic turnover data are further divided according to whether the buyer of the industrial goods has its seat in a Euro country or not.) As Figure 1 indicates the overall developments of domestic and non domestic turnover data is somewhat different. Generally the non domestic turnover index moves more dynamically.

Table 1 shows the annual rates of change of industrial turnover (mining and quarrying and manufacturing) in the European Union, the Euro area and in the Member States (working day adjusted data). Between 2001 and 2003 most countries experiences relatively low growth rates or even reductions in industrial turnover, notable exceptions were Estonia, Latvia, Romania and Slovakia where average rates reached two-digit level. In the growth phase between 2004 and 2008 these countries continued their expansion. During this period high average growth rates were also experiences in Bulgaria and Lithuania, while relatively low increases were observed in Ireland and France. In Malta industrial turnover even declined. In 2009 industrial turnover dropped in all EU countries. In those countries which had experiences a rapid expansion before the downturn was relatively high (in many cases more than 20%) but almost all countries experiences decreases of more than 10%. The only exception to this general rule was Poland where industrial turnover in 2009 decreased only moderately by – 1.8%. In the majority of countries the upswing in 2010 and 2011 was almost as swift as the downturn in 2009 and thus these countries regained or almost their level of industrial turnover of the pre-crisis year; exceptions are Cyprus, Greece, Spain, Luxembourg and Finland.

Data sources, aggregation and availability

The definition of turnover is rather straightforward. It comprises basically what is invoiced by the seller. Rebates and price deductions are taken into account as well as special charges that the customer might have to pay. Turnover does not include VAT or similar deductible taxes.

Information on industrial turnover is often collected by business surveys. However, quite a number of National Statistical Institutes rely on administrative sources, i.e. VAT declarations, to obtain the data.

According to the short-term statistics regulation data on service turnover have to be made available by the National Statistical Institutes on a monthly basis. European aggregates are calculated by summing up weighted national indices for. The weights correspond to the share of the countries in the turnover of industrial activities in the base year (2005).

All results for the indicator of turnover in industries are published on the Eurostat website.

Context

The turnover indicator in industry represents the development of sales in industry. It is therefore a value indicator which is influenced by changes in prices of the traded industrial goods and by changes of the traded volumes of goods. Apart from the influence of price changes which constitute a differences between turnover and production volumes there are also some other methodological differences, e.g. production figures include stocked good which are not yet sold. Nevertheless the connection between both indicators is relatively close as is indicated by Figure 2 which represents the [seasonally adjusted](#) monthly indicator values for turnover and production in mining, quarrying and manufacturing for the years 2000 - 2011 (2005=100).

Labour input indices overview

Data from March 2012, most recent data: Further Eurostat information, main tables and database .

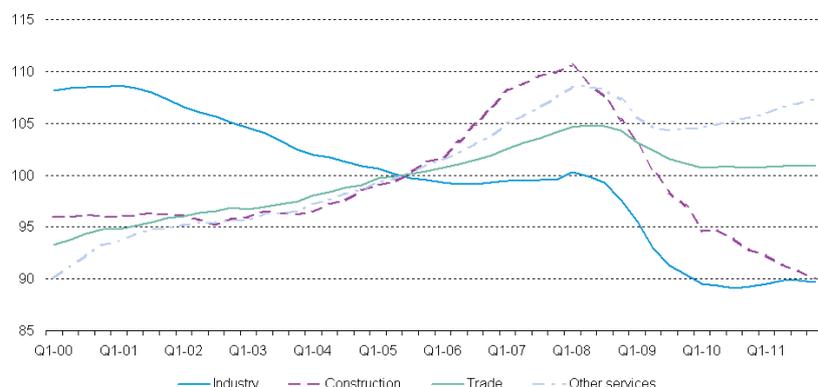

Figure 1: Number of persons employed in industry, construction, trade and other services, EU-27, seasonally adjusted, 2000-2011 (2005=100)Source: Eurostat (sts_inlb_q), (sts_colb_q), (sts_trlb_q) and (sts_selb_q)

This article presents the labour input indicators, which are [business cycle](#) indicators measuring for each quarter how the labour input used by industry, construction, trade and (other) services changes and providing important information for the analysis and forecast of economic developments in the [European Union](#) (EU) and its [Member States](#) . It introduces the labour input indicators from [short-term business statistics](#) (STS) only. Comprehensive information on employment is provided by [national accounts](#) . Further information on employment is provided by [labour market statistics](#) .

Short-term business statistics provide three different indicators for the input of labour used by European businesses:

- the number of persons employed (sometimes simply referred to as "employment");
- hours worked ("volume of work done");
- gross wages and salaries.

For industry and for construction activities all three indicators are available. For trade and (other) services short-term statistics currently only provide the number of persons employed, the coverage will be increased with the next base year change (2013).

Table 1: Employment, annual rates of change, industry, construction, trade and services, EU-27, EA-17, Member States, gross data, 2008-2011Source: Eurostat (sts_inlbgr_a), (sts_colbgr_a), (sts_trlbgr_a) and (sts_selbgr_a)

During the last decade the number of employed persons has developed very differently in the main economic sectors, industry, construction, trade and (other) services (Figure 1). In industry the number of persons employed dropped – with very few exceptions – constantly from one quarter to the next. In the second half of 2008 this decrease even gathered momentum as a result of the financial and economic crisis and only in the last quarter of 2010 and the first quarters of 2011 a very moderate increase of the industrial employment index could be observed.

In construction employment rose rapidly and peaked in the second quarter of 2009 after several years of stagnation (between 2000 and 2004). Afterwards an equally rapid decline set in which at the date of the latest statistical records was still continuing.

In trade and in services the development was less volatile. Employment in trade (wholesale trade, retail trade and trade and repair of motor vehicles) displayed a steady increase until the second quarter of 2008 and then decreased for six consecutive quarters to stabilise again at the level which it had had around 2006. In (other) services the economic crisis became visible in the employment data of the second quarter but the decline lasted only one year and a month and afterwards a still continuing steady increase set in.

For industry and construction two more labour input indicators besides employment (i.e. number of employed persons) are available: the hours worked (the actual amount of work done) and the gross wages and salaries.

Figure 2 presents the development of the three labour input indicators for industry, Figure 3 for construction activities. In both cases the indicators for employment and for hours worked develop in a very similar fashion, although during the crisis the indicator for hours worked dropped a bit faster than the indicators for the number of persons employed which suggests that measures like the reduction of overtime were taken before dismissals or postponed recruitment. There is however a marked difference between these two quantity indicators and the development of the total gross wages and salaries. (Note that that all labour input indicators are based on total numbers and not on average earnings or average working times.)

In industry there was a relatively steady increase in total gross wages and salaries despite an ongoing reduction of actual total labour input. Following the crisis the remuneration indicator recovered relatively quickly and increased again despite a constant use of total labour input.

In construction the indicators for gross wages and salaries steadily increased between 2000 and 2005 although total hours worked and total employment remained rather stable or even decreased. With the onset of the economic crisis however wages and salaries declined rapidly like hours worked and employment.

The impact of the financial and economic crisis and the extent of any subsequent recovery varied greatly between European Member States. Table 1 provides an overview of annual rates of change for the last four calendar years and thus represents the effects of the crisis and its aftermath. In 2009 and 2010 every EU Member State recorded a fall in industrial employment. In general the biggest losses were recorded in 2009, exceeding 10% in the Baltic countries, the Czech Republic, Spain, Hungary, Romania, Slovakia and Sweden. In 2011 only 11 countries experienced a decline in industrial employment while in 12 countries industrial employment increased (no data available for Ireland, Greece, Italy, the Netherlands).

Construction employment also declined in most Member States in both 2009 and 2010, the exceptions being Estonia and Portugal where increases were recorded in both years. The reductions were particularly strong (i.e. higher than 10% in both years) in the Czech Republic, Ireland, Greece, France, Lithuania, Luxembourg and Slovenia. In 2012 reductions were recorded in 13 countries and increases in 10 (no data available for Greece, Spain, Cyprus and Austria).

Employment in trade fell in most countries in 2009 and 2010 with the exceptions of Portugal where a slight increase was recorded in 2009 and in Sweden and the United Kingdom where increases were observed in 2010. However, the negative rates were in general much more moderate than in industry or construction.

In services (i.e. other services than trade) declining rates of employment in both years, 2009 and 2010, were only observed in 10 countries and the recovery from the crisis started relatively early. In 2011 only 6 countries showed a negative development in employment and in 14 countries employment in services increased (no data available for Spain, Italy, Hungary, the Netherlands, Austria, Poland and Finland).

Data sources, aggregation and availability

Short-term statistics present data on the number of persons employed. This statistical concept differs from other statistical employment concepts which are for example used by the [Labour force survey](#) or [national accounts](#). In short-term statistics the number of persons employed is collected by aggregating the number of persons employed in the statistical units, i.e. the businesses. The number of persons employed is thus in effect a number of jobs. If a person holds two jobs (e.g. regular daytime job and occasional week-end job) both jobs will be considered in the statistics. Persons employed are not identical with employees (i.e. persons who have a work contract with an employer and receive a remuneration in return for their work) but include for example unpaid family workers. Persons employed also include home workers, apprentices, persons on leave, part time workers, temporary workers and seasonal workers.

The measure of hours worked is rather comprehensive, it not only includes the normal hours but also overtime, hours worked on holidays and time which is spent on the preparation of actual work, hours spent at the working place during which no actual work is done and even short periods of rest at the work place. Thus, in broad terms, hours worked represent hours paid. However, they do not include however hours paid but not worked (e.g. paid holidays or sick leave). They do also not include time spent for meal breaks or time for commuting between home and work place.

The indicators of wages and salaries include all remuneration in cash or in kind in exchange for work including bonuses, allowances and similar payments. Social contributions payable by the employee are also included even if they are withheld and transferred to the authorities by the employer. Not included are social contributions payable by the employer and payroll taxes. The statistical sources used to establish STS labour input data vary. In some cases special surveys are used, in others data are collected from [administrative sources](#).

The STS regulation requires that Member States collect labour input data and transmit them to Eurostat at least quarterly. However for several Member States data are also available on a monthly basis ([sts_intv_m](#)).

Context

Employment is a variable that is important in both economic and social statistics. Labour input is one of the main costs of production. Employment, in its own right, is an important short-term indicator in monitoring the economy. The proportion of the working population in employment, the type of job they do and their working patterns are social variables of interest. The collection of short-term information on employment has a number of important uses:

- to evaluate the economic situation to help monitor the economic cycle;
- to calculate measures of productivity;
- to help calculate income from employment in national accounts.

The collection of information in all the Annexes of the [STS-regulations](#) give a broad economic picture and shows the balance between services and industry. Note however that to a large extent, services in STS are business services, i.e. services consumed by business like market research, business consultancy, employment activities and also transport and communication but not public services or financial services.

Retail trade volume index overview

Data from October 2012, most recent data: Further Eurostat information, main tables and database .

The index of volume of retail trade is a business indicator which measures the monthly changes of the deflated turnover of retail trade both at the level of the [European Union \(EU\)](#) and [euro area](#) , and of individual EU Member States (as well as some [candidate](#) and [EFTA](#) countries). This article provides an overview of the development of the index over recent years and describes how it is calculated.

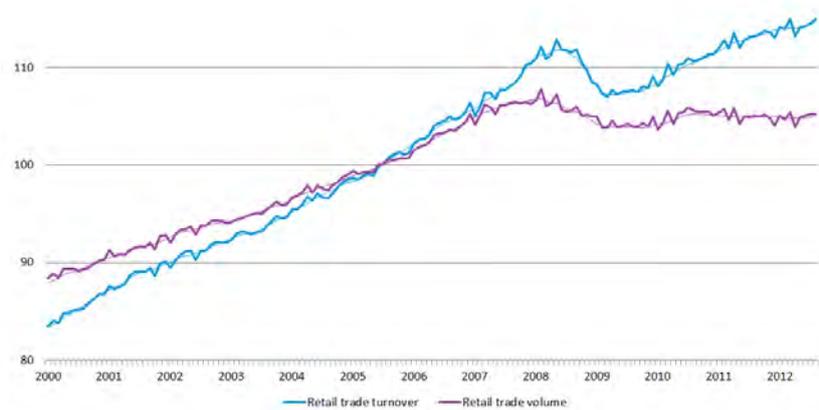

Figure 1: Retail trade volume and turnover indicators, EU-27, monthly data, seasonally adjusted (2005=100), Source: Eurostat (sts_trtu_m)

Main statistical findings

Since 2000 the volume of [retail trade](#) in the [EU-27](#) increased steadily and peaked in early 2008 (Figure 1). After that a decline set in which lasted until Mid-2009. Since then retail volume has increased again and after a year regained the level which it had around 2007. Over the recent months the increase has stopped and the volume of retail trade remained almost unchanged. Figure 1 does not only show the (real) volume of EU retail trade turnover but also the (nominal) turnover indicator which combines the development of real values and price changes. As can be seen the nominal values reacted much stronger during the crisis. However, since mid-2009 nominal turnover also increased much more than the retail trade volume and has now reached a level 2 percentage points above the pre-crisis high.

Table 1: Retail trade volume annual growth rates, working day adjusted Source: Eurostat (sts_trtugr_a)

Turnover data (but not trade volume data) are available for the whole NACE Rev. 2 section G, which includes not only retail trade (NACE Rev. 2, division 47) but also wholesale trade (NACE Rev. 2, division 46) and the sale (wholesale and retail) and repair of motor vehicles (NACE Rev. 2, division 45). Figure 2 shows the development of these turnover indicators for the EU-27. It becomes apparent that wholesale trade and the trade in motor vehicles reacted much more strongly during the crisis than the turnover of retail trade.

Figure 3 provides a breakdown of the (real) retail trade volume for the three main product groups: non-food articles; food, beverages and tobacco; and automotive fuel. The retail volume of food products (plus drinks and tobacco) reacted less strongly during the economic and financial crisis than the trade volume of non-food products. However both product groups developed in largely comparable ways. The retail volume of fuel (sold in specialised stores, i.e. filling stations) had followed a less clearer trend since the year 2000 with temporary peaks in late 2003, late 2006, early 2008 and a relatively steady decline since then.

Table 1 shows that the retail trade volume in the EU Member States generally increased during the last decennium but that the magnitude of the changes differ substantially. Between 2000 and 2007, the year before the crisis, retail trade volume doubled in Romania and Bulgaria, Estonia and Latvia (it nearly doubled in Lithuania where it increased by almost 94%). High increases of 50% or more between 2000 and 2007 could be observed in the Czech Republic, Ireland and Slovakia. In most of these countries the dynamic development stopped between 2006 and 2008. Yet the overall development of the last 11 years for these countries is still positive and the total increases in retail volume are still higher than for the rest of the EU. The development

in Poland and in Luxembourg was exceptional in that retail trade volume in these countries increased by more than 60% between 2000 and 2011 without any decrease during the years of the financial and economic crisis. In three countries, Germany, Italy and Spain, retail volume decreased between 2000 and 2011. In some other countries, Greece, Malta, the Netherlands, Austria and Portugal, the volume of retail trade is more or less the same as in 2000.

Data sources, aggregation and availability

The latest results for the development of retail trade are published in monthly [news releases](#) by Eurostat.

In principle, the [STS-Regulations](#) require short-term statistics on a deflator of sales in order to calculate volume developments from the nominal turnover data. Alternatively, the regulation foresees the possibility that Member States deliver volume of sale indicators to Eurostat which is the option that Member States have chosen. It should be noted that the volume of retail trade is conceptually different from the volume of retail trade services. The latter indicator (not available yet) does not relate to the sales as such but to the sales service. Trade volume data are available on a monthly, quarterly and annual basis, in working-day adjusted and seasonally adjusted form and as trend data. All data are either available as indices or as growth rates.

Context

In 2010 retail trade generated 468133 million EUR added value in the EU-27 (4.3% of total value added). The index of deflated retail turnover (retail trade volume) is the key European indicator for the short-term development of retail trade. The indicator is also one of the ' [Principal European economic indicators \(PEEI\)](#) ' which are used to monitor and steer economic and monetary policies in the EU and in the euro area.

Services producer price index overview

Data from June 2012, most recent data: Further Eurostat information, main tables and database .

This article presents the [services producer price index \(SPPI\)](#) (also called service output price index), measuring prices of services, as it is calculated and used at the level of the [European Union \(EU\)](#) and its Member States.

The services producer price index is a [business cycle](#) indicator which provides information on the development of prices for numerous service industries. This information is used for the analysis of [inflation](#) and its sources, but also for the [deflation](#) of value measures in the service sector.

This article presents services producer prices for all uses (B2All indicators), i.e. services consumed by private consumers, by business consumers and others. However, the bulk of the service industries covered by the indicator are those which are, as a matter of fact, mainly demanded by businesses (B2B indicator), they include for example freight transport, legal and accounting services, advertising and market research (see below).

Producer prices (output prices) represent the prices from the point of view of the producer. The prices are transaction prices and take into account discounts, rebates, surcharges and similar price determining elements but not product taxes.

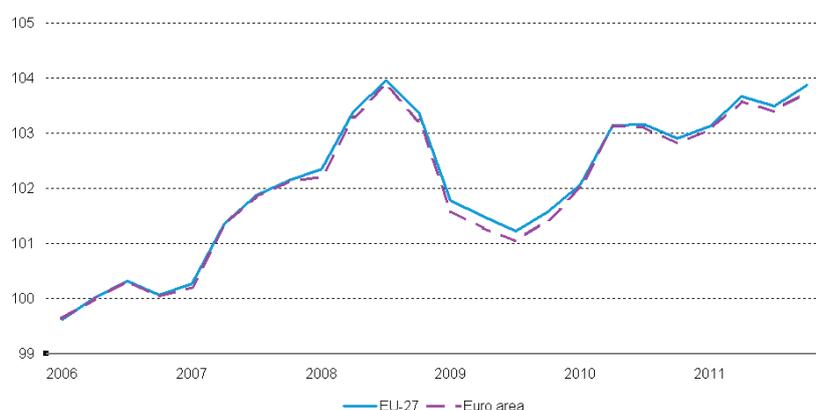

Figure 1: Service producer prices as requested by the STS-regulation (NACE groups 49.4 – 81.2), EU-27 (2006=100), Source: Eurostat (sts_sepp_q)

Main statistical findings

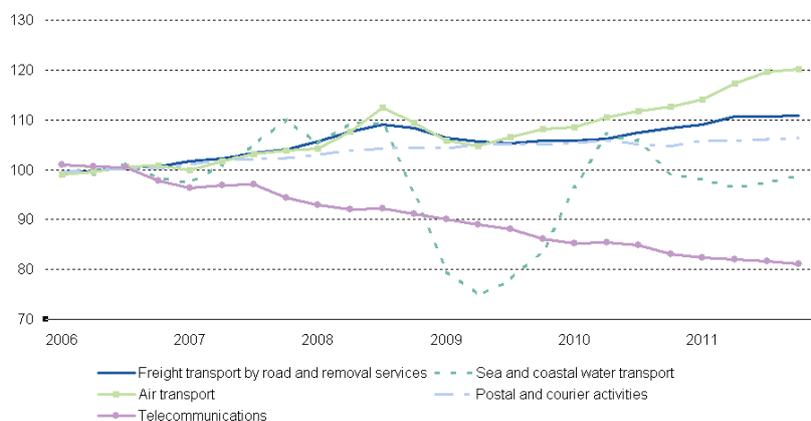

Figure 2: Service output prices for transport and communication services (NACE divisions/groups 49.4, 50.1_50.2, 51, 53, 61), EU-27 (2006=100), Source: Eurostat (sts_sepp_q)

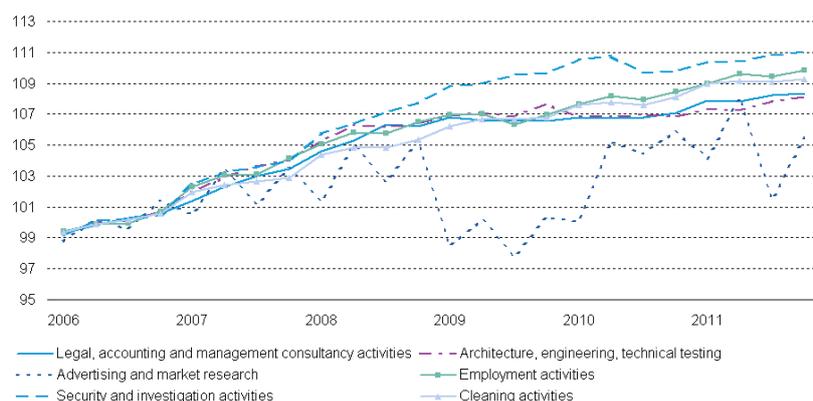

Figure 3: Service producer prices for selected business services, (NACE divisions/groups 69_70.2, 71, 73, 78, 80, 81.2), EU-27 (2006=100), Source: Eurostat (sts_sepp_q)

Figure 1 presents aggregated services producer prices for the EU-27 and the Euro area. The indicators combine all service areas for which services producer prices are collected under the short-term statistics Regulation 1165/98, i.e. road, water and air transport, telecommunication services, legal and accounting services, management consulting, advertising and market research, employment, security and cleaning services. Between their introduction in 2006 and mid-2008 aggregated services producer prices showed a relatively steady increase. During the economic and financial crisis prices fell but started increasing again in mid-2009. By the end of 2011 service producer prices had almost regained their pre-crisis level.

With few exceptions service producer prices develop in a relatively steady manner. Figure 2 provides an overview of prices for transport and communication services. The main exceptions from the overall stable trends are telecommunication services which – like many technology related activities – have displayed a continuous downward trend for all years for which data are available. For sea and costal water transport output prices underwent a rather special development with a pronounced fall between the third quarter of 2008 and the second quarter of 2009, possibly reflecting over-capacities at the beginning of the crisis, and an equally steep upturn on the following periods. Despite their relative small share in the total STS service aggregate (3.8%) the step decline in sea and costal water transport prices (by almost 35 percentage points) is the main reason behind the drop in the prices of the STS service aggregates (Figure 1). Since the second quarter of 2010 prices for sea and costal water transport started falling again. Similar to the development in the water transport sector prices in air transport started to decline in late 2008. Air transport appears to be a sector which is also relatively sensitive to the overall economic climate. Prices started to increase again in the second half of 2009.

For many other business services (Figure 3) the general development since 2006 is more stable than for transport and communication. It can be assumed that many of these services (e.g. cleaning, security) are based on long-term contracts. Moreover, some services such as legal and accounting services may be considered largely indispensable by businesses and were not or not significantly reduced during the financial crisis so that there was no incentive for service providers to adjust prices. The only exception to this general trend are the prices for advertising and market research which dropped by almost 7% in the first quarter of 2009 but have since then almost regained their pre-crisis level.

Data sources and availability

Information on output prices of services is generally collected by business surveys. However for some prices other sources are used, for example information from regulatory bodies for telecommunication prices or for legal services. Web surveys are also used to collect certain price information. The service price indices are calculated on a quarterly basis, data are available from 2006 on. Note that the base year for the price indices is 2006 (not 2005 as for other short-term statistics indicators). The collection of price data for services poses a number of statistical problems due to the special nature of services. In particular it is difficult to ascertain the quality of services and therefore difficult to collect price data for services of a comparable nature and quality over time. Measurement problems are also due to the fact that services are often consumed on production and that many services are unique and tailor-made for the client.

Context

Services are an important part of European economies and contribute substantially to output and employment. Traditionally short-term statistics mainly covered industrial and construction activities. When the monetary union was prepared it became clear that better and more complete data for the service sector were necessary. Regulation 1158/2005 of 6 July 2005 amended the short-term statistics regulation of 1998 ([short-term statistics Regulation 1165/98](#)) and introduced the collection of output service prices on a quarterly basis. First data became available in 2009. The service output price index is today one of the [Principal European Economic Indicators \(PEEIs\)](#) which are used to monitor and steer economic policy in the EU and in the euro area. Aggregate service producer price indicators for the total of services covered by the STS-regulation have only been published since June 2012.

Services turnover index overview

Data from January 2013, most recent data: Further Eurostat information, main tables and database .

This article provides an overview of the development of the services turnover indicator in the [European Union \(EU\)](#) , the [euro area](#) and the European [Member states](#) over recent years and describes how it is calculated. The index of turnover in (other) services is a [business cycle](#) indicator which measures the quarterly development of turnover in the European service industries with the exception of services in retail and wholesale trade for which a [separate indicator](#) exists (hence "other" services; in this article the "other" will be omitted for easier readability).

The data presented in this article are taken from European [short-term statistics \(STS\)](#) . The data on services collected under the [short-term statistics regulation](#) encompass mainly – but not only (see below) – services consumed by businesses, therefore they are often referred to as " [business services](#) " .

Table 1: Annual growth rate for the turnover in services (%), Source: Eurostat (sts_setugr_a)

Main statistical findings

Between 2000 and 2008 the turnover of European service industries (as covered by the STS regulation) expanded on a relatively steady growth path. A rapid decline set in after the second quarter of 2008 (in the euro area already one quarter earlier) and within a year turnover in the EU-27 declined by 12%. In the third quarter of 2009 a steady recovery set in and the latest data (third quarter 2011) indicate that the pre-crisis level has already been regained for the EU-27 (Figure 1). Since around mid-2011, the level of service turnover has remained almost unchanged.

Short-term statistics cover – with some exceptions – the following five groups according to NACE Rev. 2 (NACE code in brackets): transportation and storage (H), accommodation and food services (I), information and communication services (J), professional, scientific and technical activities (M) and administrative and support services (N). The development of the turnover for these main service activities is represented in Figure 2. Transport and storage, professional, scientific and technical as well as administrative and support services show a rather similar development. They are also the biggest of the five service industries in terms of value added and therefore largely influence the development of turnover for total services. Accommodation and food services and likewise information and communication services show a steadier turnover development.

Table 1 provides a breakdown of the development (growth rates) of the service turnover in the Member States of the EU and also for Croatia and Turkey. In 2009 all EU Member States experienced a decline in services, in many countries the negative rates of change even reached double-digit level (in the Baltic countries negative rates even surpassed -20%). In Estonia, Ireland, Spain, and Latvia service turnover already began to decline in 2008.

Table 1 also indicates very different dynamics in the turnover development between Member States. On average the service turnover increased by around 55% between 2000 and 2011. In Malta, the country with the lowest growth, it increased by only 11% over eleven years, i.e. 0.9% per year on average. Other examples of countries with a relatively low turnover growth were Germany, Greece and Spain (all with an average 2.3% between 2000 and 2011). In Romania, the country with the fastest growth, the turnover index increased by more than 570% over eleven years or 18.9% on average. Other countries which experienced a rapid growth were Luxembourg (average 13.0%), Latvia (average 12.4%), and Bulgaria (average 10.6%).

In most countries the indicator of service turnover peaked at the third quarter of 2008 and reached a low about one year later. Afterwards service turnover in most countries recovered again relatively steadily. Most countries have already reached or even surpassed their pre-crisis levels. Special developments can be observed in Greece where the level of turnover has steadily declined since 2008 and in Poland where the crisis only caused a rather shallow dip in the development of service turnover.

Data sources, aggregation and availability

The definition of turnover is rather straightforward. It comprises basically what is invoiced by the seller. Rebates and price deductions are taken into account as well as special charges that the customer might have to pay. Turnover does not include [VAT](#) or similar deductible taxes.

Information on service turnover is most often collected by business surveys. However, quite a number of National Statistical Institutes rely on administrative sources, i.e. VAT declarations, to obtain the data. There are also cases where both methods are used; for example bigger enterprises might be asked to contribute to a survey whereas the data for smaller enterprises are collected from VAT registers.

According to the short-term statistics regulation data on service turnover have to be made available by the National Statistical Institutes at least on a quarterly basis. However, around half of the Member States collect these data (at least for some services) on a monthly basis. Not in all cases can these data be published by [Eurostat](#) (e.g. for reasons of confidentiality). Countries for which aggregated monthly service turnover data are published are Spain, France, Luxembourg, Portugal, Romania, Slovenia, Finland and the United Kingdom. European aggregates are calculated by summing up weighted national indices for individual service activities. The weights correspond to the share of the countries in the turnover of service activities in the base year.

All results for the indicator of turnover in services are published on the [Eurostat website](#).

Context

The turnover index for services is one of the [Principal European economic indicators](#) . It is one of the relatively few available indicators for services and is used to analyse business cycle trends in the service industry and as input for [national accounts statistics](#) .

Table 2: Annual growth rates for construction, 2007-2011(%) - Source: Eurostat (sts_coprgr_a) and (sts_coprgr_a)

This article examines recent statistics in relation to developments for both industry and construction in the European Union (EU). Short-term business statistics (STS) are provided in the form of indices that allow the most rapid assessment of the economic climate within industry and construction, providing a first evaluation of recent developments for a range of activities. STS show developments over time, and so may be used to calculate rates of change, typically showing comparisons with the month or quarter before, or the same period of the previous year. As such, STS do not provide information on the level of activity, such as the monetary value of output (value added or turnover), or actual prices.

Main statistical findings

Industry

The impact of the financial and economic crisis and the subsequent recovery of the EU-27's industrial economy can be clearly seen in two of the main industrial indicators, namely the [industrial production index](#) and the [index for industrial domestic output prices](#). Over several years there was relatively stable output and price growth across the EU-27 (see Figure 1), which was interrupted from the second half of 2007 as price growth accelerated, while industrial output slowed. The EU-27's industrial production index saw its month-on-month rate of change turn negative in March 2008, while the index for domestic output prices peaked six months later in July 2008. The fall in output lasted more than one year, returning to a positive rate of change in June 2009, while domestic output prices reached their lowest level in July 2009 and started a run of relatively sustained increases from October 2009.

The decline in industrial output in the EU-27 from its relative peak in February 2008 was particularly steep (-17.2%), as the relative trough recorded in May 2009 was the lowest level of output since May 1999. By contrast, although industrial output prices in July 2009 were 8.1% lower than at their relative peak a year earlier, they remained in line with the price level recorded in September and October 2007 prior to the financial and economic crisis; in part, price developments continued to reflect the relatively high price of crude oil and associated energy-related and intermediate products. Domestic output prices for industry rose by 6.7% in 2011, which was almost twice as fast as they had increased in 2010 (3.5%).

Industrial [import prices](#) for the euro area peaked in July 2008, regardless of whether imports were from outside the euro area or from other Member States within the euro area (see Figure 2). Thereafter, prices of imports from within the euro area fell over a nine month period by a total of 7.5%, whereas the prices of imports from outside the euro area fell by a total of 15.3% over the same period. Since their low point in the spring of 2009 prices for imports from within the euro area increased by 12.3% through to April 2011, since when they remained relatively stable through to July 2012 (latest available data at the time of writing). Starting from the same low point (May 2009), import prices from outside the euro area increased by 26.6% through to March 2012 and remained relatively stable (with a slight decrease) through until July 2012. Prices for imports passed their pre-crisis highs (of July 2008) in December 2010 for imports from within the euro area and in January 2011 for imports from outside of the euro area.

The downturn in industrial activity was widespread, illustrated by the fact that every EU Member State recorded lower output in 2009 than in 2008, with falls ranging from -3.7% in Poland to -23.9% in Estonia (see Table 1). The subsequent recovery was also widespread, as only Cyprus and Greece recorded a further contraction in activity during 2010, with growth rates peaking at 23.0% in Estonia. Although output continued to expand in 2011 in most of the EU Member States, the contraction in Greece and Cyprus persisted while five other EU Member States also recorded a contraction in their output. The index of production for the EU-27 rose, on average, by 3.2% in 2011, which was just less than half the rate of increase experienced in 2010 (6.8% growth in industrial output).

The downturn in activity during the financial and economic crisis was spread across almost the full range of industrial activities: in 2009 there was just one industrial activity (at the NACE Rev. 2 division level) that reported continued growth within the EU-27, as the output of pharmaceutical products and preparations rose by 3.5% compared with the year before. The recovery in 2010 was also relatively widespread: there were seven exceptions (at the NACE Rev. 2 division level), where output continued to contract in 2010, most notably for the manufacture of tobacco products, with a loss of 5.8%. The number of activities that recorded a fall in output increased to ten in 2011 (see Figure 3), with four of the seven activities that had contracted in 2010 continuing their downward path, while a further six activities followed expansion in 2010 with contraction in 2011. The relatively strong contraction (-14.1%) in output recorded for the extraction of crude petroleum and natural gas reflects, at least in part, a long-term decline in North Sea reserves of these products.

Construction

The downturn in activity for construction within the EU-27 lasted longer than for industry. Furthermore, after stabilising in 2010 and even displaying a slight upturn in the first half of 2011, a second downturn started in the third quarter of 2011 and has not yet (at the time of writing) shown signs of stabilising.

Construction output in the EU-27 peaked in March 2007 and fell gradually for five months. This initial downturn was followed by a slight, temporary recovery until January 2008, after which substantial falls in

construction activity were recorded, reaching a low in February 2010, just under three years after the initial downturn. Between January 2008 and February 2010 the index of production for construction in the EU-27 fell by 13.4% overall, deteriorating to a level not seen since October 1999. From this low point at the beginning of 2010 construction output remained relatively stable over the next 18 months to the middle of 2011. In August 2011 the second downturn in construction output started and by June 2012 (latest data available at the time of writing) output had fallen a further 6.0% from the mid-2011 level; between February 2008 and June 2012 construction output fell by a total of 18.1%.

The construction of buildings is the dominant part of construction output, and unsurprisingly output for building work followed a similar path to the overall indicator for construction, although the magnitude of the contraction from the beginning of 2007 to the beginning of 2010 was slightly greater, totalling 16.5% in the EU-27 (see Figure 4). For civil engineering the developments were less clear cut. From March to December 2008, civil engineering output in the EU-27 fell in a similar manner to the developments seen for building output. However, there followed a substantial increase in January 2009, mainly due to a massive expansion in civil engineering work in Spain. Civil engineering output then resumed its downward path through much of 2009, before contracting rapidly between February and March 2010 after which it was relatively unchanged through to the end of 2010. A short recovery in civil engineering output in the first five months of 2011 was followed by a return to a downward path in line with that observed for construction as a whole. By June 2012 civil engineering output in the EU-27 was 12.7% lower than it had been in February 2008.

The long and deep downturn in construction activity was widespread within the EU-27, illustrated by the fact that every Member State except Poland experienced at least one year of contraction in construction output during the four latest years (2008 to 2011) for which data are available. In 2008 a total of 13 EU Member States recorded a contraction in construction output and this number rose to 24 in 2009, before dropping back to 21 in 2010. The latest annual figures show that a small majority (14) of the EU Member States reported an increase in construction output in 2011.

The Czech Republic and Italy recorded negative rates of change in relation to their construction activity in all four years (2008 to 2011); while the ongoing downturn has been even longer in Ireland and Spain where five consecutive negative annual rates of change were recorded (from 2007 to 2011), while in Hungary the sequence is now six years (2006 to 2011), and in Portugal the last positive annual rate of change was recorded in 2001. Construction output declined by 10% or more in Portugal, Bulgaria, Ireland and Spain in 2011, and by 20% or more in Slovenia and Greece. In contrast, Latvia, Germany and Poland reported an increase in construction output above 10% in 2011, while output increased by more than 20% in Lithuania and Estonia.

Data sources and availability

Short-term business statistics (STS) are compiled within the scope of the STS [Regulation 1165/98](#) of 19 May 1998 concerning short-term statistics. The STS Regulation brought major changes and improvements in the availability and timeliness of indicators which followed its implementation. The STS Regulation has been amended and adjusted to meet emerging users' needs – generally in relation to monetary union and more specifically to the requirements of the [European Central Bank \(ECB\)](#).

Indicators common to industry and construction include the production index and labour input indicators concerning [employment](#), wages and salaries, and [hours worked](#). For industry there are additional STS indicators concerning turnover and output prices, which are compiled as a total and also distinguishing between domestic and non-domestic markets, with a further analysis of non-domestic markets between [euro area](#) and non-euro area markets. In a similar manner, there are industrial import prices, with a distinction between imports from euro area and non-euro area markets. For construction activities there is a distinction in the production index between building and civil engineering, while additional indicators are collected on building permits, as well as construction cost and price indices.

The presentation of short-term statistics may take a variety of different forms. Gross or unadjusted indices are the basic form of an index. [Working-day adjustment](#) takes into account the calendar nature of a given month in order to adjust the index. The number of working days for a given month depends on: the timing of certain public holidays (Easter can fall in March or in April depending on the year); the possible overlap of certain public holidays and non-working days (1 May can fall on a Sunday); whether or not a year is a leap year, and other reasons. [Seasonal adjustment](#) aims, after adjusting for calendar effects, to take into account the impact of known seasonal factors that have been observed in the past. For example, in the case of the production

index, annual summer holidays have a negative impact on industrial production. The [trend](#) is a slow variation over a long period of years, generally associated with the structural causes of the phenomenon in question. The cycle is a quasi-periodic oscillation. It is characterised by alternating periods of higher and lower rates of change possibly, but not always, involving expansion and contraction. Generally, if this component of the time series is relatively important, the trend cycle series is a better series for the analysis of longer-term developments. However, this advantage is less clear when analysing very recent developments. This is because trend cycle values for recent periods may have greater revisions than the equivalent seasonally adjusted values. Hence, the latter may be more appropriate for the analysis of very recent developments; this is particularly true around turning points.

Depending on the indicator in question, the EU Member States are required to transmit unadjusted or adjusted data to Eurostat. In the case that Member States transmit unadjusted data, then Eurostat calculates the seasonal adjustment. The Member States' national statistical authorities are responsible for data collection and the calculation of national time series. Eurostat is responsible for the EU-27 and euro area aggregations.

NACE Rev. 2 is the latest version of the statistical classification of economic activities and has been implemented in STS during 2009. This involved not just changing data compilation practices to use NACE Rev. 2 but also recalculating or estimating a time series in NACE Rev. 2, normally back to the year 2000. Simultaneously with the introduction of NACE Rev. 2, a new base year (2005) was adopted for STS indices to better reflect the economic structure; previously indices were presented with 2000 as the base year. The next base year change, namely to a base year of 2010=100, is due to be introduced during 2013.

Context

The profile and use of STS is expanding rapidly, as information flows have become global and the latest news release for an indicator may have significant effects on financial markets, or decisions that are taken by central banks and business leaders. STS are a key resource for those who follow developments in the business cycle, or for those who wish to trace recent developments within a particular industry, construction or service.

Some of the most important STS indicators are a set of [principal European economic indicators \(PEEIs\)](#) that are essential to the ECB for conducting monetary policy within the euro area. Three PEEIs concern industrial short-term business statistics: production, output prices of the domestic market and import prices. A further two PEEIs concern construction short-term business statistics: [production](#) and [building permits](#) .

Methods for compiling PEEIs in short-term business statistics

Eurostat compiles European Union (EU) and euro area infra-annual economic statistics relevant for short-term economic analysis. Among these, a list of indicators called PEEIs (abbreviated from 'principal European economic indicators') has been identified by key users as being of prime importance for monetary and economic policies of the euro area.

This article first provides an insight into the recently released 2010 PEEI in focus report on service producer price indices (SPPIs), then informs on how to access all the PEEI in focus reports produced since 2005.

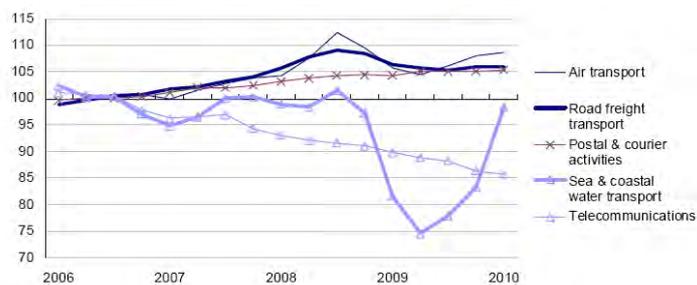

Figure 1: Producer price indices for selected services, EU-27 (2006=100) Eurostat (sts_sepp_q)

	NACE Rev. 2	Label
Transportation & storage	49.4	Freight transport by road & removal services
	50.1+50.2	Sea & coastal water transport - passenger & freight
	51	Air transport - passenger & freight
	52.1	Warehousing & storage
	52.24	Cargo handling
	53.1	Postal activities under universal service obligation
	53.2	Other postal & courier activities
Information & communication	61	Telecommunications
	62	Computer programming, consultancy & related activities
	63.1 63.9	Data processing, hosting & related activities, web portals Other information service activities
Professional, scientific & technical activities	69+70.2	Legal & accounting activities & management consultancy activities
	71	Architectural & engineering activities; technical testing & analysis
	73	Advertising & market research
Administrative & support services	78	Employment activities
	80	Security & investigation activities
	81.2	Cleaning activities

Table 1: Activities for which the STS Regulation requires SPPIs.PNG

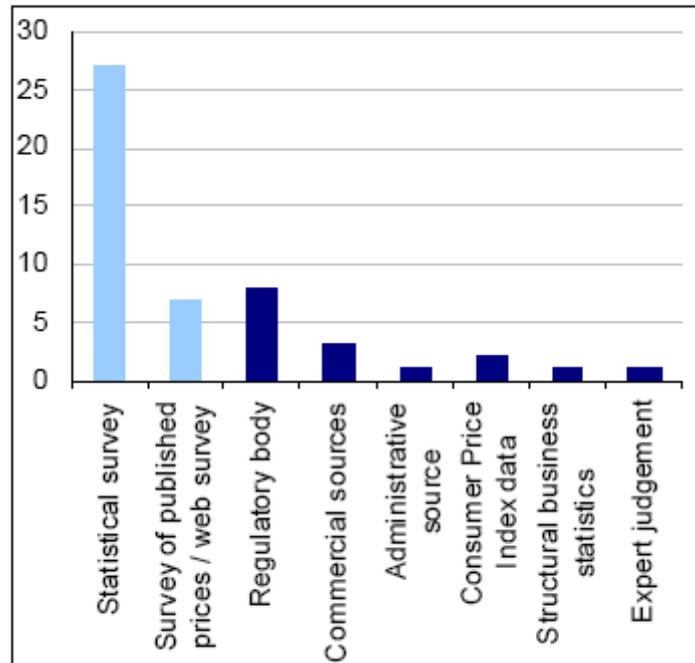

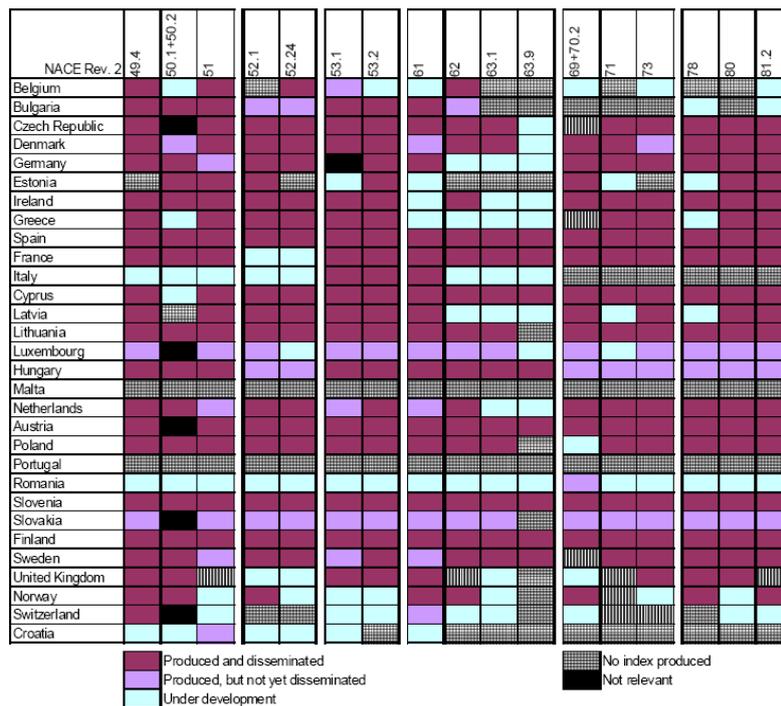

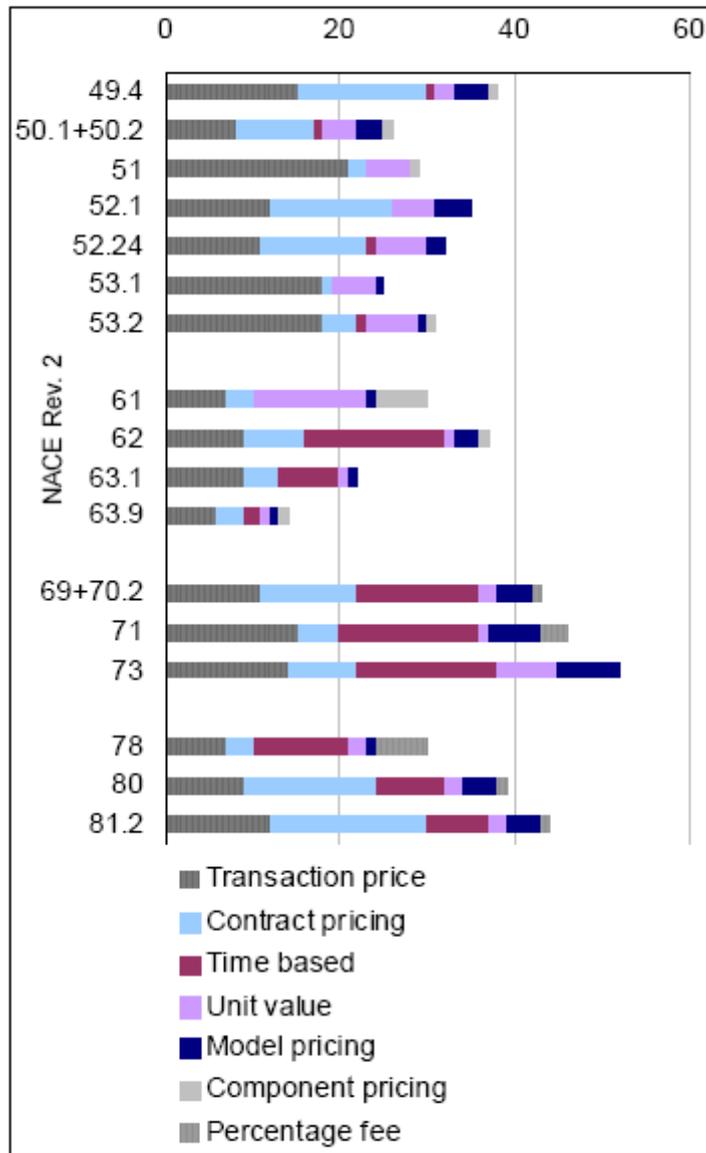

Figure 2: Sources of services price data (count of countries- multiple answers possible)

(1) Cells with vertical stripes indicate that within that activity SPPIs for different services are at different stages of development; for example the SPPi for Division 69 might be produced and published while that for Group 70.2 is still under development.

Table 2: Status of development of SPPIs by activity

See Table 1 for explanation of NACE Rev. 2 codes.

Figure 3: Pricing methods (count of countries- multiple answers possible)

	Pricing method	Observation
Output methods	Transaction price for a repeated service, this might be a list price	Observe the price of a service product
	Contract pricing (real model, real prices) for repeated services in a long-term contract	Observe the total price of a real bundle of service products
	Component pricing (also bill method): weighted components (e.g. fictitious mobile phone user profile) valued with real prices for each component of the bundle	Observe the total price of a fictitious bundle of service products
	Model pricing (also virtual price): fictitious service product (or bundle of service products) that may never have existed for which a quote (fictitious price) is given	Estimate a total price of one fictitious service product or a fictitious bundle of service products
	Unit value : calculated from value of sales (or turnover) divided by the quantity of the service provided	Observe quantity and value and derive an average price
	Percentage fee	Observe prices/values of a related product
Time method	Time based method (also hourly rate or charge out rates)	Cost / hour

Table 3: Explanation of pricing methods

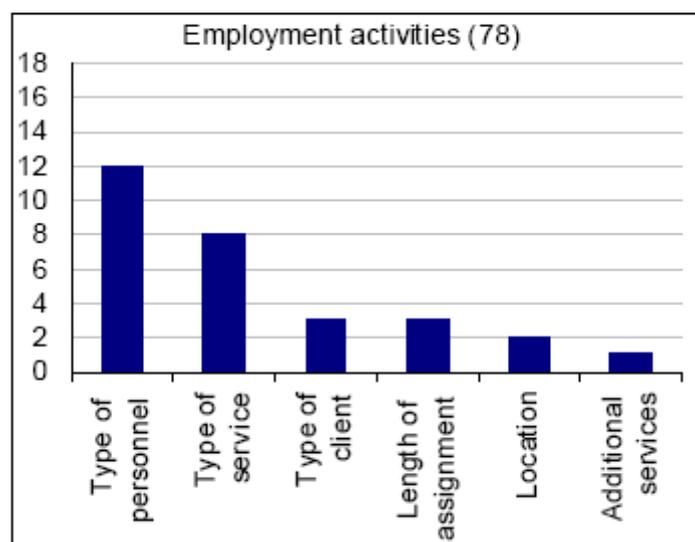

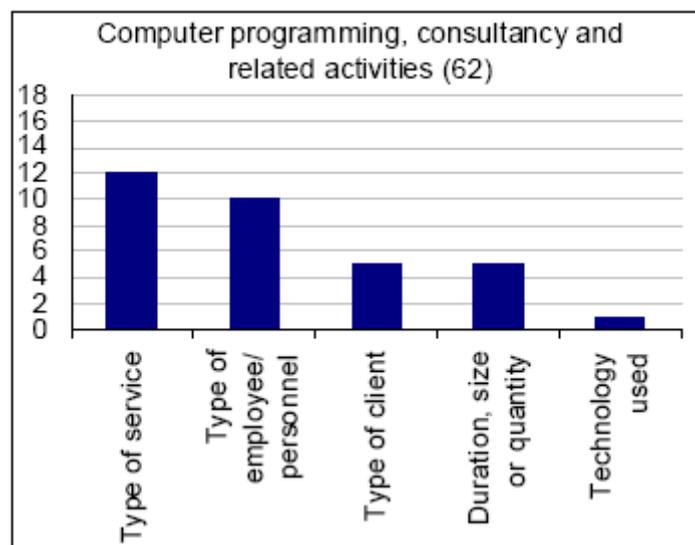

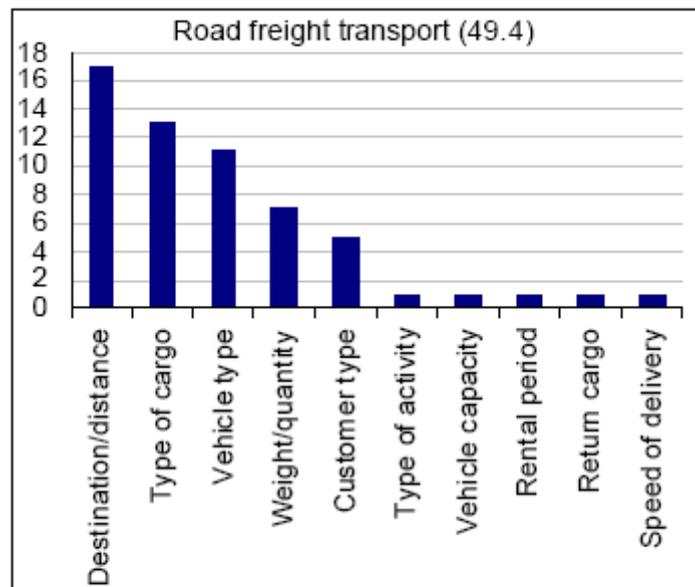

Figure 4: Price characteristics used (count of countries- multiple answers possible)

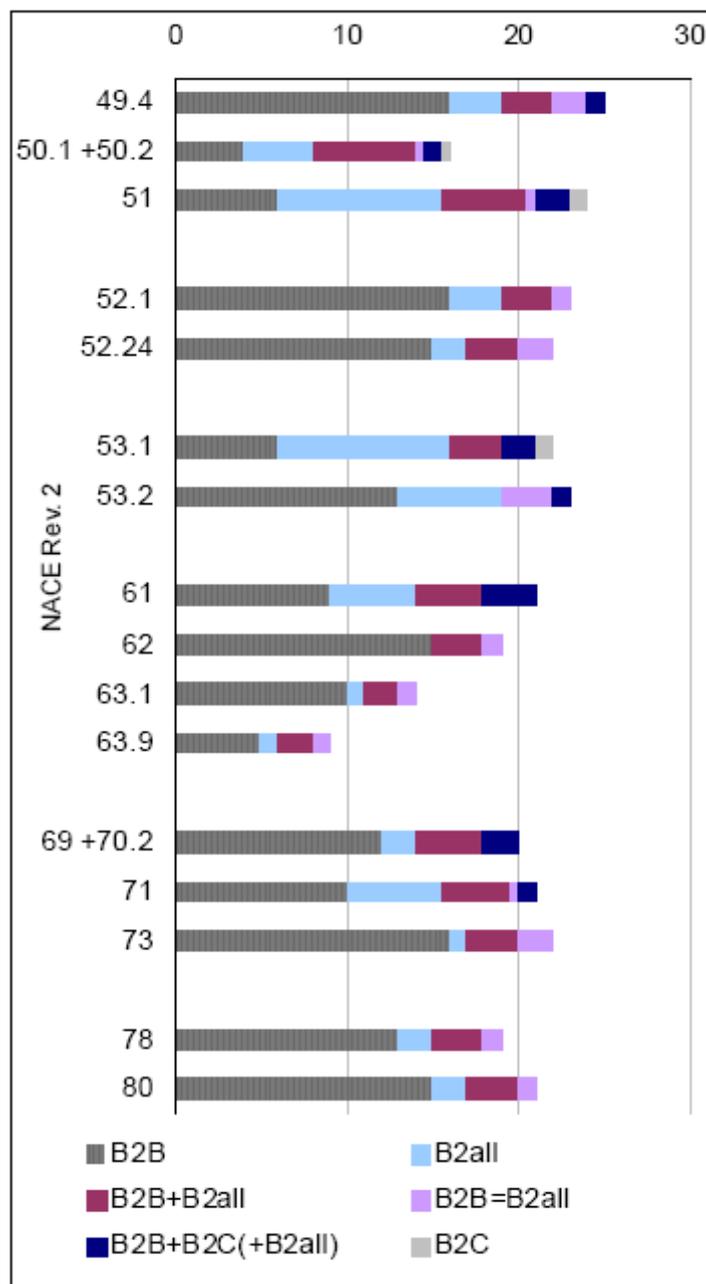

Figure 5: Coverage of business and consumer markets

Indicator	Year collected
Industrial production index	2004 / 2005
Volume of sales index: retail trade	2006
Industrial producer price index	2007
Index of production: construction	2008
Turnover index: services	2009
Services producer price index	2010

Table 4: History of PEEI in focus reports

Indicator	Specific subjects
Industrial production index	Basic type of data collected (turnover, production quantities, hours worked etc.); deflation; use of weights, working-day adjustment
Volume of sales index: retail trade	Treatment of VAT; source of deflator
Industrial producer price index	Selection of products and respondents; quality change; updating of the sample
Index of production: construction	Basic type of data collected (turnover, hours worked etc.); deflation; treatment of building and civil engineering
Turnover index: services	Compilation of deflated turnover
Services producer price index	Pricing method used; coverage; selection of products and respondents

Table 5: Points of specific interest.PNG

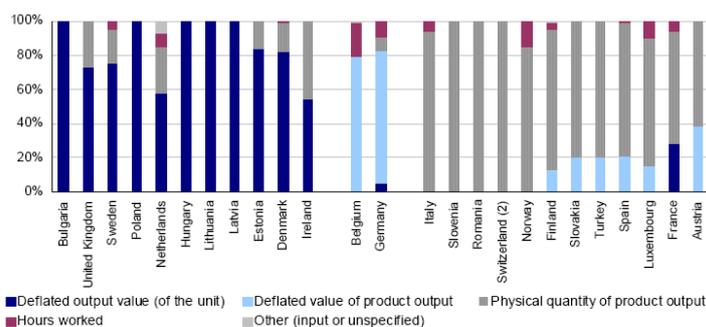

Figure 10: Industrial production index, basic methods used (% weighted by value added)

Main statistical findings

Nine PEEIs concern [short-term business statistics](#) (STS), namely indices covering: industrial production, domestic industrial producer prices, industrial import prices, production in construction, building permits, the volume of sales in retail trade, service turnover, and services producer prices.

Since 2005 [Eurostat](#) has collected information from countries on the sources and methods they use to compile the PEEIs and synthesises into a report on one PEEI within STS every year. These reports became known as the PEEI in focus reports; they are valuable background information for users and for compilers alike.

For 2010 the index chosen for the PEEI in focus report was the services producer price index (SPPI). The 2010 PEEI in focus questionnaire was returned by all of the EU Member States, as well as Norway, Switzerland and Croatia. The information provided generally relates to practices in the year 2009.

Service producer price indices (SPPIs)

SPPIs are intended to trace price movements that reflect market supply and demand conditions in order to facilitate the analysis of macro-economic conditions and to monitor inflationary pressures. They also serve as a deflator to convert the value of service output into volume measures.

Developing service price indices is a difficult task as service output is often hard to identify and even more difficult to measure reliably, as services may be tailored or bundled in different ways for different users.

The STS Regulation specifies a list of activities for which SPPIs should be developed (see Table 1) between 2005 and the end of 2010. Together Eurostat and the OECD developed the Methodological guide for developing producer price indices for services to assist countries.

Source of data All countries reported using statistical surveys to collect service producer price data. One quarter of countries reported collecting at least some data from published prices, of which several were surveys of web-based prices, for example for air transport or telecommunications. A similar number of countries reported using data from regulatory authorities, and this was also particularly common for telecommunications. Three countries reported using commercial sources, and in two cases it was specified that this concerned advertising activities.

Two countries specified using data from consumer prices, and it may well be that the use of this data may be more widespread: many other countries combine consumer price indices with SPPIs for business markets to produce a total PPI

Production and development of SPPIs Table 2 shows the coverage of SPPIs included in the PEEI in focus report indicating for which activities SPPIs are produced and which are in various stages of development: this

information was collected at the beginning of 2010; since then development work may have started for some activities and been completed for others. Spain, Hungary, Austria, Slovenia, Finland and Sweden produce SPPIs for all of the activities (excluding those that are not relevant, such as sea and coastal water transport in landlocked countries). A further nine countries have indices produced or under development in all activities shown. Six more countries have almost complete coverage in terms of either production or development, with just one activity not yet in the development phase, and this is nearly always NACE Rev. 2 Group 63.9 (other information service activities). The remaining countries have several activities where they have not yet started development.

In terms of activities, SPPIs are most widely produced in postal and courier activities (NACE Rev. 2 Division 53) and transport activities (Divisions 49 to 51), and production is less common in information and communication services (Divisions 61 to 63).

The SPPI data that has been provided to Eurostat is available from Eurostat's online database.

Pricing methods Various methods are used because of the diversity of different types of service output: a brief explanation is given in Table 3, while Figure 3 indicates the extent to which the methods are used.

In road freight, water transport, cargo handling and storage, contract pricing and transaction prices are both commonly used. Air transport and postal and courier services are dominated by transaction pricing, reflecting the relatively abundant on-line information. Security and investigation activities, as well as cleaning activities rely more heavily on contract pricing, because of the often regular and standardised nature of this work. For professional, scientific and technical activities, as well as for computer programming, consultancy and related activities and also employment activities, timebased methods (often an hourly rate) are commonly used.

Model pricing is occasionally used in nearly all activities but rarely by more than a few countries, and is most common in professional, scientific and technical activities. Methods based on percentage fees are used in most professional, scientific and technical activities and administrative and support service activities, but not elsewhere. Equally, the reverse is true of component pricing, which is used in most transportation and storage activities, as well as information and communication services, but not in the other services. Although used to some extent in every activity, only in telecommunications is the use of unit values the most common pricing method.

Price determining characteristics In order to follow price developments over time it is essential to precisely specify the unit of service output to be priced in successive months. Figure 4 gives three examples of the types of specifications commonly used by the countries, as included in the PEEI in focus report.

Markets covered For SPPIs the STS Regulation focused on services to businesses, and so indices referred to as B2B (business to business) were required, in other words showing price developments for business customers. In some activities (for instance air passenger transport) it is particularly difficult to compile B2B indices separately from B2all (business to all) indices, and as can be seen from Figure 5 the most common situation is for countries to produce either a B2B index or a B2all index. A number of countries compile both a B2B and a B2all index, and some also produce a B2C (business to consumer) index as well.

Previous PEEI in focus reports

PEEI in focus reports have so far been produced for six of the nine PEEIs within short-term business statistics. These have been produced on a rotating basis, with one report produced each year since 2005 – see Table 4.

It is intended to complete this set of reports to cover industrial new orders, industrial import prices and building permits, and then to determine the procedure for updating all reports.

Reports available on CIRCA The PEEI in focus reports are all available from the STS Circa groups which can be accessed through the methodology page on [Eurostat's portal for short-term statistics](#) – in CIRCA the reports can be found in the Library, under the heading STS Quality.

The earliest reports are now 4-5 years old and methodological changes may have accompanied the change in classification (to NACE Rev. 2) and base year (to 2005) that took place during 2008 and 2009: the 2009 report on the turnover index in services was the first of these PEEI in focus reports to be produced after the migration to NACE Rev. 2.

Producing the reports The annual cycle of producing the PEEI in focus reports starts with the design of a questionnaire to collect information from countries on their practices for the selected indicator. The questionnaires for different indicators have many points in common, for example information on the sample frame and sample design, frequency of data collection and definition of the variables. Nevertheless, each of the indicators has some methodological points that are of specific interest: some examples are presented in Table 5.

The questionnaire is sent to all of the Member States, Norway, Switzerland and the candidate countries. Based on the information provided by each country a report is compiled that aims to provide an overview of the methods used.

As an illustration, on page 7 there is one example of the analysis from each of the PEEI in focus reports produced between 2004 and 2009.

Context

Eurostat compiles European Union and euro area infra-annual economic statistics relevant for short-term economic analysis. Among these, a list of indicators, called Principal European Economic Indicators (PEEIs) has been identified by key users as being of prime importance for the conduct of monetary and economic policy of the euro area.

Nine PEEIs concern short-term business statistics (STS), namely indices covering: industrial production, domestic industrial producer prices, industrial import prices, production in construction, building permits, the volume of sales in retail trade, service turnover, and services producer prices.

Since 2005 Eurostat has collected information from countries on the sources and methods they use to compile the PEEIs and synthesises into a report on one PEEI within STS every year. These reports became known as the PEEI in focus reports; they are valuable background information for users and for compilers alike. For 2010 the index chosen for the PEEI in focus report was the services producer price index (SPPI). The 2010 PEEI in focus questionnaire was returned by all of the EU Member States, as well as Norway, Switzerland and Croatia. The information provided generally relates to practices in the year 2009.

Table 2: Annual growth rates for the volume of sales index, retail trade, 2001-2011 (1)(%) - Source: Eurostat (sts_trtu_a)

This article examines recent statistics in relation to developments for service activities in the [European Union \(EU\)](#). [Short-term business statistics \(STS\)](#) are provided in the form of indices that allow the rapid assessment of the economic climate within services, providing a first evaluation of recent developments for a range of activities. Traditionally, short-term business statistics were concentrated on industrial and construction activities, and to a lesser extent retail trade. Since the middle of the 1990s, major developments in official statistics within the EU have seen short-term data collection efforts focus increasingly on services.

Main statistical findings

Services turnover fell by 8.4% in the [EU-27](#) in 2009 compared with the year before but rebounded in 2010 and 2011 increasing by 5.0% and 5.3% respectively. Among service activities (at the [NACE Rev. 2](#) section level), the fastest rates of turnover growth in 2011 were recorded for transportation and storage activities (7.5%), professional, scientific and technical activities (6.2%) and administrative and support services (5.9%).

As can be seen from Figure 1, by the second quarter of 2012 the level of sales for most services activities had returned to close to their respective levels recorded prior to the financial and economic crisis and in some cases had exceeded these previous peaks. However, the rate of turnover growth generally subsided in the first half of 2012 and a majority of services activities recorded a slight decline in turnover.

Having peaked at various stages of 2008, turnover for all six of the services shown in Figure 1 reached a low point in the second or third quarter of 2009 in the EU-27. From these lows, the strongest growth in turnover through to the second quarter of 2012 was recorded for transportation and storage services (16.8%), which brought its turnover to a level that was some 2.8% above its pre-crisis peak. Administrative and support services as well as professional, scientific and technical activities also recorded double-digit growth between their mid-crisis low and their latest levels (second quarter 2012) which in both cases were also above their pre-crisis highs. Despite more modest turnover growth (5.6%) since its mid-crisis low, turnover for EU-27 information and communication services was still 1.0% higher in the second quarter of 2012 than it had been at its pre-crisis peak. In the second quarter of 2012 turnover for the two remaining service activities shown in Figure 1 remained slightly below their pre-crisis peaks: 2.4% lower for accommodation and food services (despite growth of 12.3% since the mid-crisis low); and 1.5% lower for distributive trades (after growth of 5.6% since its mid-crisis low).

While turnover shows sales in current prices, the volume of sales indicates the situation once price changes have been removed. The decline in the volume of sales in retail trade in 2009 reached -1.6% in the EU-27, but this activity rebounded with growth of 0.9% in 2010 before remaining stable (-0.1%) in 2011. A monthly series (see Figure 2) shows the volume of retail sales peaked in the EU-27 in February 2008 and fell a total of 2.7% through to October 2009; positive rates of change returned with an increase of 1.3% by September 2010, after which the volume of sales index remained stable. Some parts of retail trade were still experiencing a decline in their respective volume of sales in the first half of 2012, notably the large activity of retailing of food, beverages and tobacco. In contrast, the specialised retail sale of information and telecommunications equipment as well as medical, cosmetic and toilet articles recorded increases in turnover throughout 2010, 2011 and the first half of 2012, after relatively mild contractions in their respective volumes of sales during the financial and economic crisis. The specialised retail sale of textiles, clothing, footwear and leather articles had seen a similar development until the end of 2010 when growth slowed and the volume of sales started to decrease gently.

Among the services for which an EU-27 price index is shown in Figures 3a and 3b two stand out as having atypical developments – telecommunications and sea and coastal water transport. Since 2006 (the beginning of the series) EU-27 output prices for telecommunications have been on a steady downward path and in just over six years they fell by a total of 20.7%. Output prices for sea and coastal water transport are remarkable for their relatively high volatility, in particular the fall and subsequent rise in prices related to the financial and economic crisis. The net impact of these movements was that prices in the first quarter of 2012 were within 2.4% of their level at the beginning of the series. Most of the other services recorded overall price increases in a range of 7% to 13% during the six years shown, with air transport output prices increasing at a faster pace, rising by an amount close to 22%.

The developments for services turnover observed for the EU-27 as a whole for the period 2009 to 2011 were common across many of the individual EU Member States. Every Member State (Italy, not available) recorded a fall in services turnover in 2009; all except Greece recorded an increase in 2010; all except Greece, Portugal, Hungary and Spain recorded an increase in 2011, with growth exceeding 10% in Poland and Luxembourg and exceeding 15% in the [Baltic Member States](#) .

Table 1 provides an analysis of the two latest rates of change for turnover for each of the services sections covered by short-term business statistics. Growth rates in excess of 20% were recorded in 2011 for two or more activities in each of the Baltic Member States, as well as for administrative and supporting activities in Ireland and Slovakia. In contrast, turnover fell by nearly 20% in 2011 for professional, scientific and technical activities in Hungary, and by just over 30% for transportation and storage in Cyprus. In 2011 Greece recorded falling turnover in each of the six services shown in Table 1, while 11 EU Member States recorded growth for each of these services.

The fluctuating development in the volume of sales index in retail trade observed for the EU-27 between 2009 and 2011 was not regularly reproduced across the EU Member States. Instead, Luxembourg, Sweden and the United Kingdom recorded an increase for the volume of sales in retail trade in all three years. In contrast, nine Member States recorded decreases in 2009, 2010 and 2011, with this downward sequence extending to four years (with the inclusion of 2008) for Denmark, Ireland, Spain and the Netherlands. Despite being a relatively modest increase, the 0.3% growth in Hungary in 2011 was notable as it marked the first annual increase in the Hungarian volume of sales index since 2006.

Data sources and availability

Short-term business statistics (STS) on services are compiled within the same methodological framework as short-term statistics on industry and construction. The article on [short-term developments in industry and construction](#) provides additional information on: the STS Regulation; the different forms of presentation of indices, namely gross, working-day adjusted, seasonally adjusted, and trend; the implementation of NACE Rev. 2; and the five-yearly exercise to rebase STS indices to a new base year.

The turnover index and the employment index are compiled for retail trade and for other services. For retail trade one additional indicator is provided, namely the volume index of retail sales, which is effectively a deflated turnover index. Furthermore, service output price indices have been developed for a selection of services in recent years and work is ongoing to produce a services production index.

The index of turnover shows the development of sales in value terms. Note that prices for some services have actually been falling, perhaps due to market liberalisation and increased competition (for example, telecommunications and other technology-related activities). In such cases, the rapid growth rates observed for turnover value indices for some activities would be even greater in volume terms.

Retail trade indices have particular importance because of the role of retail trade as an interface between producers and final customers, allowing retail sales turnover and volume of sales indices to be used as short-term indicators for final domestic demand by households. The volume measure of the retail trade turnover index is more commonly referred to as the index of the volume of (retail) sales. To eliminate the price effect on turnover in retail trade, a deflator of sales is used. This deflator is an index with a similar methodology to that of an output price index, but it is adapted specifically for retail trade; it reflects price changes in the goods sold rather than those in the retail sales service provided.

Context

Some of the most important STS indicators are a set of [principal European economic indicators \(PEEIs\)](#) that are essential to the [European Central Bank \(ECB\)](#) for conducting monetary policy within the euro area. Three PEEIs concern services short-term business statistics, namely indices covering: the volume of sales in retail trade, turnover in other services, and output prices of other services.

Tourism introduced

Europe is a major [tourist](#) destination and six of the [European Union \(EU\)](#) Member States are in the world's top-10 destinations for holiday-makers. As a result, [tourism](#) plays an important role in terms of its economic and employment potential, while presenting social and environmental implications. These two characteristics drive the demand for reliable and harmonised statistics within this field.

Tourism can also be a significant factor in the development of European regions. Infrastructure created for tourism purposes contributes to local development, while jobs that are created or maintained can help counteract industrial or rural decline. ' [Sustainable](#) tourism' involves the preservation and enhancement of cultural and natural heritage, ranging from the arts, to local gastronomy, or the preservation of biodiversity.

A new policy approach for tourism is being developed. The [European Commission](#) adopted in 2006 a Communication entitled ' [A renewed EU tourism policy: towards a stronger partnership for European tourism](#) '. The document addressed a range of challenges that will shape tourism in the coming years, including:

- Europe's ageing population;
- growing external competition;
- consumer demand for more specialised tourism;
- the need to develop more sustainable and environmentally-friendly tourism practices.

The document argued that a more competitive tourism industry and sustainable destinations would contribute further to the success of the renewed [Lisbon Strategy](#) , tourist satisfaction, and to securing Europe's position as the world's leading tourist destination.

This was followed by a Communication from the European Commission in October 2007 – ' [Agenda for a sustainable and competitive European tourism](#) ' – which outlined the future steps for promoting the sustainability of European tourism. The communication made further contributions to the implementation of the renewed Lisbon strategy for growth and jobs and the renewed sustainable development strategy, through addressing stakeholders involved in European tourism. The sustainable management of destinations, the integration of sustainability issues by businesses, and sustainability awareness of tourists form the framework of the actions proposed.

[Eurostat](#) publishes tourism statistics relating to capacity and occupancy of [tourist accommodation establishments](#) and tourism demand by European residents, collected and compiled by the national statistical authorities.

Tourism statistics

Data from June 2012, most recent data: Further Eurostat information, Main tables and Database .

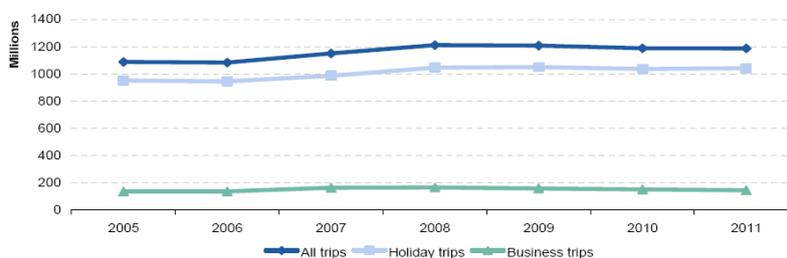

This article takes a look at recent statistics on [tourism](#) in the [European Union \(EU\)](#) , in particular the final results for 2010-2011 evolutions. The focus is on holiday trips made by EU residents, whether or not involving a stay at [tourist accommodation](#) establishments but it also looks at trends in [nights spent](#) at hotels and similar establishments by tourists regardless of their country of residence.

Over the past four years, the number of holiday trips residents have made has remained more or less stable at just over one billion. In 2011, there was even a slight rise, by 0.5%, compared with 2010. More than three out of four trips were domestic, but long outbound trips accounted for half of all tourist expenditure in 2011.

Main statistical findings

Europeans made 5 million more holiday trips in 2011 but spent less days in their destination

Figure 1 shows percentage changes in the main indicators for tourism demand in 2011 compared with 2010. The reported growth of 0.5% in the total number of holiday trips was the result of an increase in both the number of domestic holiday trips (+0.3%) and holiday trips abroad (+1.2%) - see also Table 1. Stronger growth in trips abroad can be linked to the significant fall in such trips during the first years of the crisis, while domestic trips were less affected.

The increase in the number of trips made did not necessarily mean more nights spent away. Overall, the number of nights spent away even fell by -0.1% in 2011, especially for domestic trips (-0.7%). As a result, trips were on average shorter than a year earlier.

European tourists spent slightly more money (+0.7%) on holiday trips in 2011. Even if total spending was distributed over a higher number of trips, spending on an average trip rose by 0.5%. Expenditure per night grew by 1.4%. Both spending per trip and per night rose relatively more for domestic trips than for outbound trips.

Trips of EU residents: impact of crisis

Crisis has significant impact on business trips, but not on holiday trips

Figure 2 shows that the number of tourism trips has dropped slightly since 2008, hovering around 1.2 billion trips per year. Though the number of holiday trips stayed just above 1 billion, the number of trips for work-related reasons dropped significantly, from 166 million in 2008 to 145 million in 2011, contracting by -12.7%.

For holiday trips, the biggest impact was observed in 2009, with a significant drop in the number of nights spent away (see Figure 3). EU residents made about the same number of trips, but they were shorter than before. For business trips, both the number of trips as well as their length fell steadily. Europeans made fewer work-related trips than before the start of the crisis and the trips they did make were shorter.

Trips of EU residents: 2011 patterns

More than three out of four trips were domestic, but long outbound trips accounted for half of all tourist expenditure

In 2011, most trips Europeans made were to a destination within the Member State where they live (76%), with fewer than one in four trips abroad (see Table 1 and Table 2). Big differences were observed across the EU. Some residents spent less than half of their holidays in their own country. That was the case for Belgium (26%), Luxembourg (less than 1%), the Netherlands (48%) and Slovenia (44%). Others stayed 'at home' for more than nine out of 10 holiday trips in 2011. That was very much the case for residents of Spain (92%), Portugal (91%) and Romania (93%).

Even if domestic trips still accounted for most holiday trips, outbound trips grew relatively faster in 2011. This recent growth partly made up for the partial substitution of outbound trips with domestic trips over the recent years. There was a significant rise in the number of long outbound trips of at least four overnight stays (+1.7%), while short trips abroad decreased by -0.7%.

For domestic trips, there was a sharper increase in long trips (+0.5%) than for short trips of one to three nights (0.2%). In the EU, short domestic trips accounted for half of all holiday trips in 2011. Long domestic trips took 26% of the market share, while long and short outbound trips represented 18% and 5% respectively. In only eight EU Member States did the number of long trips exceed the number of short trips. In the Netherlands, Belgium and Luxembourg, more than 60% of all trips were long.

EU residents' spending on holidays grew by 0.7% in 2011. Nearly half of that rise came from higher spending on long domestic trips (while spending on short domestic trips shrank). The two segments with the poorest evolution in terms of nights spent, namely long domestic trips (-1.2%) and short outbound trips (+0.1%), recorded the fastest growth in expenditure (+1.3% and +3.1% respectively, resulting in growth of average expenditure by +3.7% and +4.0% respectively). On average, Europeans spent € 64 per holiday night, € 50 during domestic trips and € 82 during outbound trips.

Trips of EU residents: participation of the population to tourism

Half of all EU residents made one or more summer holiday trips

Most EU residents went on holiday in the third quarter, as expected (see Table 3). During the summer months of July, August and September, nearly half made at least one holiday trip, and more than one in three made a holiday trip of four nights or more. The third quarter was the most popular for all countries, except Malta.

The biggest seasonal differences in tourism were observed in Cyprus, Greece and Bulgaria, where the number of people taking holidays in the peak quarter exceeded that for the bottom quarter by a factor of 6, 4 and 3 respectively.

In the Nordic countries, Denmark, Finland, Sweden and Norway, seasonal differences were less pronounced, with more than half the population going on holiday in nearly every quarter of 2011.

Trips of EU residents: main means of accommodation

Only one in four trips spent at hotels or similar establishments

In 2011, most trips were spent at so-called private tourist accommodation. This type of accommodation includes rented rooms in family homes, dwellings rented from private individuals or professional agencies, but also second homes and accommodation provided for free by friends or relatives. Stays at hotels or similar establishments accounted for almost 26% of holiday trips, while other collective accommodation such as holiday dwellings, campsites or youth hostels were used for nearly 10% of holiday trips.

There were significant differences, depending on destination. For domestic trips, more than two-thirds of holidays were spent at private accommodation and less than 20% at hotels or similar establishments. For outbound trips, the opposite was the case, with hotels or similar establishments accounting for 52.8% and a significant 14.1% of holiday trips spent in rented holiday dwellings, at campsites or youth hostels.

Nights spent in hotels and similar establishments in EU-27

Accommodation sector shows clear recovery in 2011

The previous section looked at the type of accommodation chosen by EU residents on their holiday trips. Figure 5 looks at trends in nights spent at hotels or similar establishments by tourists, regardless of their country of residence. In 2011, the number of nights was well above the previous peak registered in 2007. Also, considering nights spent by residents and by non-residents separately, both series exceeded the pre-crisis level.

Data sources and availability

Representativeness of the EU-27 estimates

- Holiday trips made by EU residents, nights spent and average length of trips (Figure 1, Table 1): aggregate data based on 24 Member States (not including Ireland, Greece and Malta), these Member States represent 98.3% of the total population (aged 15 or over) of the European Union.
- Tourist expenditure by EU residents (Figure 1, Table 1): aggregate data based on 23 Member States (not including Ireland, Greece, Spain and Malta), these Member States represent 93.4% of the total population (aged 15 or over) of the European Union.

": data unavailable or unreliable

Context

In June 2010, the European Commission released a Communication entitled "[Europe, the world's No 1 tourist destination - a new political framework for tourism in Europe](#)". One of the challenges and opportunities facing the European tourism industry is the seasonal distribution of demand for tourism. Better use of existing tourist

infrastructure and staff in the low season could help businesses improve their productivity and benefit from a more stable and motivated workforce. Extending the tourism season or spreading tourism activities more evenly throughout the year can significantly boost the [sustainability](#) and [competitiveness](#) of European tourist destinations.

Tourism statistics - nights spent in tourist accommodation establishments

Data from February 2013. Most recent data: Further Eurostat information, Main tables and Database .

This article focuses on the short-term evolutions in the [nights spent](#) in [tourist accommodation establishments](#) in the [European Union \(EU\)](#) . The data for the most recent [reference month](#) available are compared with the same month of the previous year, in addition - and to smoothen fluctuations - data from January to the most recent available month are compared with the same period one year earlier.

With the adoption of [Regulation 692/2011](#) concerning European statistics on tourism, timeliness of accommodation statistics has significantly improved. As of 2012, monthly data are transmitted to [Eurostat](#) within eight weeks after the reference month. This article is the first publication of November 2012 data.

Note: 2012 EU-27 estimate made for the purpose of this publication, based on 11 months' data.

Source: Eurostat (online data codes: tour_occ_nim and tour_occ_ninat)

Figure 3: Nights spent in EU-27 tourist accommodation establishments, 2004-2012 (index:2004=100) - Source: Eurostat (tour_occ_nim), (tour_occ_ninat)

Main statistical findings

In November 2012, compared with November 2011, 0.6 million more nights (+0.6%) were spent in tourist accommodation establishments in the European Union. This increase was exclusively due to non-residents (tourists travelling outside their country of residence) (+0.6 million nights, +1.8%) while the number of nights spent by residents remained relatively stable (-0.1%). In the segment of [hotels and similar accommodation](#) a decrease by 0.2 million nights (-0.3%) was observed in November 2012, compared with November 2011 (see Figure 1 and Table 1).

Looking at the eleven months' period from January to November 2012 a decrease of -0.5% was recorded in the number of nights spent in tourist accommodation establishments compared with the previous year, while the segment of hotels and similar accommodation recorded a drop of -0.3%.

First results for 2012

Estimates for the entire year can be obtained by applying the above evolutions for the first eleven months of the year to december 2011.

Despite the slight drop in 2012, the total number of nights spent in tourist accommodation establishments in the European Union remains well above the level of 2007, the year before the crisis began to affect the tourism sector (see figure 3).

Data sources and availability

Representativeness of the EU-27 estimates

EU-27 estimate made for the purpose of this publication, not including Ireland, Greece, Latvia, Lithuania, Luxembourg, Hungary, Romania, Slovenia and the United Kingdom, because of methodological changes between 2011 and 2012. The 18 Member States included in the EU-27 estimate represent 82.1% of the total nights spent in tourist accommodation establishments in the European Union.

Symbols ":" data unavailable or unreliable.

Context

The EU is a major tourist destination, with six Member States among the world's top ten destinations for holidaymakers. Tourism is an important activity in the EU which has the potential to contribute towards employment and economic growth, as well as to development in rural, peripheral or less-developed areas. These characteristics drive the demand for reliable and harmonised statistics within this field, as well as within the wider context of regional policy and sustainable development policy areas.

Tourism statistics - summer season occupancy

Data from February 2012, most recent data: Further Eurostat information, Main tables and Database .

This article analyses the [tourism](#) trends of the 2011 summer season in the [European Union \(EU\)](#) Member States and [EFTA](#) countries. Tourism recorded positive growth rates in most countries, compared with the same period in 2010. This trend is confirmed both by the number of [nights spent in hotels and similar establishments](#) , and by the net [occupancy rates of bed places](#) in these establishments.

Summer season tourism trends in 2011

Comparing the monthly figures for the 2011 summer season with the previous year, nearly 35 million more nights (+4.8%) were spent in hotels and similar establishments in the European Union. The highest increases were observed in Bulgaria (+21.1%), Romania (+17.5%) and Lithuania (+16.8%), while Malta and Italy reported a decline (-1.9% and -1.2% respectively).

71.0% of the nights in hotels and similar establishments in the EU-27 were spent in five countries: Spain (18.8%), Italy (17.8%), Germany (13.1%), France (11.4%) and the United Kingdom (9.7%). The most popular destinations for non-residents (tourists travelling outside their country of residence) were Spain, Italy and Greece, together accounting for more than half of all nights spent by non-residents in the EU-27.

Nights spent by residents and non-residents

In the European Union, the number of nights spent by non-residents in hotels and similar establishments strongly increased by 8.3% in summer 2011 compared with the same period of 2010. This tendency was observed in all Member States, except for Malta (-1.4%) and Sweden (-1.3%). In Malta and Cyprus, the share of non-residents was more than 90%, (96.9% and 91.2% respectively), while it was particularly low in Romania (14.7%).

In terms of nights spent by residents (tourists travelling inside their country of residence) in hotels and similar establishments, domestic tourism increased during the 2011 summer season in the European Union (+1.8%). This was also true in most Member States, with the exception of Malta (-15.1%), Cyprus (-14.6%), Greece (-9.3%), Italy (-4.8%), Hungary (-2.8%) and Slovenia (-1.3%).

Net occupancy rates of bed places

Compared with the same months of the previous year, net occupancy rates of bed places in the European Union increased by 2.5 percentage points during the 2011 summer season. These rates ranged from 28.4% in Romania (June) to 91.7% in Cyprus (August).

In most of the countries August was the month with the highest occupancy rates. With 91.7%, 83.4% and 79.1% respectively, Cyprus, Malta and Greece were the countries with the highest net occupancy rates during their peak summer month.

Data sources and availability

Symbols ":" data unavailable or unreliable

Context

In the 2011 summer season, tourism recorded positive growth rates in most of the EU and EFTA countries, compared with the same period in 2010. This trend is confirmed both by the number of nights spent in hotels and similar establishments, and by the net occupancy rates of bed-places in these establishments.

Winter season tourism trends in 2011-2012

Comparing the monthly figures for the 2011-2012 winter season with the same period of the previous year, 14.5 million more nights (+2.6%) were spent in hotels and similar establishments in the European Union.

The highest increase was observed in Latvia (+11.4%), while a decline was reported by Portugal (-4.3%), Italy (-4.2%), Cyprus (-4.2%), Malta (-3.5%) and Spain (-0.7%).

Almost three-quarters of the total nights in hotels and similar establishments in the EU-27 were spent in five countries: Germany (17.5%), Spain (16.3%), France (14.3%), Italy (13.5%) and the United Kingdom (12.2%).

The most popular destinations for tourists travelling outside their own country during the winter season 2011-

2012 were Spain, Italy and Austria, together accounting for nearly half of all nights spent by non-residents in the EU-27.

Nights spent by residents and non-residents

With the exception of Malta, Cyprus and Italy, the number of nights spent by non residents (tourists travelling outside their own country) increased in the EU-27 Member States in the winter season 2011-2012.

The highest share of non-residents was recorded in Malta, Luxembourg and Cyprus (93.2%, 92.6% and 90.0% respectively), while it was particularly low in Sweden (20.3%), Romania (21.0%) and Germany (22.0%).

In terms of nights spent by residents (people travelling inside their own country) in hotels and similar establishments, domestic tourism increased during the 2011-2012 winter season in most Member States, with the exception of Luxembourg (-19.4%), Portugal (-12.1%), Cyprus (-9.5%), Italy (-7.8%), Spain (-3.2%) and Slovenia (-1.8%).

Net occupancy rates of bed places

Compared with the same months of the previous year, net occupancy rates of bed places in the European Union increased by 0.3 percentage points during the 2011-2012 winter season. These rates ranged from 9.7% in Luxembourg (December) to 63.5% in Austria (February).

In most of the countries April (Easter) was the month with the highest occupancy rates. Austria, Malta, the Netherlands and Spain reached net occupancy rates of bed places of more than 50% in the peak month, while in Luxembourg, Bulgaria, Romania, Slovakia and Lithuania the corresponding rates were less than 30%.

Data sources and availability

Symbols ":" data unavailable or unreliable

Context

In the 2011-12 winter season, tourism recorded positive growth rates in most of the EU and EFTA countries, compared with the same period in 2010-2011. This trend is confirmed both by the number of nights spent in hotels and similar establishments, and by the net occupancy rates of bed-places in these establishments.

Figure 5: Seasonal variation(1) in occupancy of collective tourist accommodation and in employment (by sector), 2009, EU-27

This analysis from the point of view of the supply side complements another article on [seasonality in tourism demand](#) in which the seasonal bias in tourism demand is discussed.

Main statistical findings

Nights spent

July and August account for one third of all annual nights spent in accommodation establishments in the EU

The tourist accommodation sector experiences strong seasonal fluctuations. Nearly one in three nights spent in tourist accommodation establishments during 2009 was recorded in July or August. However, the number of persons employed in this industry appears to vary less.

Tourist accommodation sector

Seasonal fluctuations were particularly high in the tourist accommodation sector where 33.2% of annual nights spent away were recorded in the two peak months, July and August

The monthly accommodation statistics for 2009 showed a significant seasonal bias for arrivals and number of nights spent in tourist accommodation (see Figure 1 and Table 1). The number of arrivals were a bit more evenly spread over the year than the number of nights spent away, mainly due to the concentration of longer stays in July and August. Both figures peaked in August. The number of arrivals in the peak month was 2.6 times higher than the number of arrivals in the slowest month (January) while the number of nights spent was 3.8 times higher in the peak month than in the slowest month (again January). In terms of nights spent, the two summer months accounted for one third (33.2%) of all nights spent in tourist accommodation in 2009. The period from June to September represented more than half (53.1%) of all nights spent away during the year (see also Figure 3).

Seasonality in tourism seemed to be much higher from a supply side perspective (i.e. using accommodation statistics) than from the demand side perspective (see article "[Seasonality in tourism demand](#)"). While the first — by definition — includes only tourism flows into (paid) tourist accommodation, the latter also includes trips where the accommodation was not paid for, such as stays with relatives and friends or stays at owned dwellings (e.g. second residences). These types of trips may be more frequent or regular and therefore less concentrated in the busiest tourism months of the year.

At Member State level

In the Alpine countries Austria, Switzerland and Liechtenstein, the seasonal pattern was smoothed as these countries have a second peak season in winter

The overall situation at EU level shown in Figure 1 aggregates data from countries with a very different seasonal profile. For each country, the monthly share in the annual number of nights spent in tourist accommodation is listed in Table 1. The average of the absolute deviations of monthly data points from their mean can be used to measure seasonal variation. It gives an idea of how much the monthly figures deviate from even distribution (i.e. a perfectly even spread of nights spent away over the 12 months of the year).

The eight countries with the highest seasonal variation in 2009 overlap with the set of countries where at least one month took up a share of more than 20% of the annual nights spent (see Figure 2a), except Cyprus. This group included typical Mediterranean destinations and Scandinavian countries (namely Sweden and Denmark, who both had a particularly high peak in July). However, there was no absolute geographical rule since other countries located in this region showed a much lower seasonal variation.

To put the seasonal pattern of this group in perspective, Figure 2b shows the countries with the lowest seasonal variation. This group included Malta, while the other Mediterranean island state Cyprus showed a more pronounced seasonal pattern. When comparing the monthly series for these two Member States, they both seemed to have a very important summer season, but the slowdown during the winter was much more pronounced in Cyprus than in Malta (see Table 1). While activity in the winter months for the Maltese accommodation sector

was comparable to the European average, the winter scores for Cyprus were the lowest, together with Greece and Croatia.

A particular phenomenon leading to lower seasonality was observed in the Alpine countries Austria, Switzerland and Liechtenstein. When looking at the months with a share above the expected share if the distribution were even (i.e. each month has a share of 8.3% — or 1/12th of the annual total), these countries appeared to have higher figures in two separate periods of the year. In addition to a peak season during the summer months, these countries had a second peak season during the winter months. To a lesser extent, a similar phenomenon was recorded for Finland and Slovakia. This double peak pattern is clearly depicted in Figure 2c. In Belgium, a second peak season (or local high) was observed during the spring months April and May (followed by a slowdown in June before the summer peak).

Another way to evaluate seasonality is to look at the difference between the peak and the trough months (see Table 2).

On average for the EU-27, this ratio was 3.8. This means that occupancy (in nights spent) of accommodation establishments was nearly 4 times higher in the peak month (August) than in the trough month (November). Using this measure, the countries with the highest seasonality were again Greece and Croatia. In Greece, more than 13 million nights spent were recorded in the peak month August, while just under 1 million nights spent were recorded in January. In Croatia, more than 10 million nights spent away were recorded in August, 35 times more than the 300 000 nights spent in December. The third highest ratio was found in Denmark, where the number of nights spent in the peak month exceeded that of the slowest month by a factor of 9.3. In Denmark, 23.9% of all nights spent were recorded in July — the highest monthly share in the EU in 2009. In the European Union, below average (under 3) seasonality ratios were found in Latvia (2.4), Finland (2.5), Germany (2.7), Estonia (2.8) and Slovakia (2.9). The winter season peak also narrowed the deviation between the peak and trough months in Liechtenstein (2.3) and Switzerland (2.5).

A similar approach is used in Table 3. However, here the period of observation is extended to the two peak and two slowest months. At EU-27 level, the peak months of July and August accounted for 33% of nights away in tourist accommodation. At the other end, the slowest months (November and January) represented less than 10% of the annual nights spent away. The two peak months were most pronounced in Bulgaria (43%), France (42%), Greece (41%) and Italy (40%) while the two slowest months were least significant in Greece (3%), Cyprus (5%), Bulgaria and Denmark (6%). Again, an exceptionally high seasonal influence was observed in Croatia where July and August represented more than half (54%) of all nights away and February and December each represented less than 1% (see also Table 1).

In all EU Member States, the peak months for the tourist accommodation sector were July and August, except in Austria (February and August) and Finland (June and July).

By accommodation type

Seasonality in the tourist accommodation sector was less pronounced for establishments operated as a hotel than for other types of establishments

In the previous sections, the tourist accommodation sector was analysed as a whole. A breakdown by type of accommodation reveals that in 2009, seasonal fluctuations were less prominent for [hotels and similar establishments](#) than for other tourist accommodation such as campsites (see Table 4 and Figure 3). For ease of presentation, the monthly data is grouped per quarter in Table 4. In all countries except Malta, the peak for the hotels (37% in the third quarter, on average for the EU) was lower than the peak for other types of tourist accommodation (56% in the third quarter, on average for the EU). In only three countries, hotels and similar establishments had to rely on the third quarter for more than half of their overnight stays: Bulgaria (54%), Greece (55%) and Croatia (57%). Establishments active in other segments of the accommodation sector had a much higher peak in the period July to September.

The double peak pattern for Austria is also reflected in the data in Table 4, showing that the number of nights spent in hotels and similar establishments in the first quarter (32% of the annual total) outnumbered the traditional peak quarter, the third quarter (31%). The monthly distribution broken down by type of accommodation (see Figure 3) indicates that the summer peak could be partly related to higher seasonality for other tourist accommodation. This subsector includes tourist campsites, which depend more much on the weather

(and are often closed in winter). However, the seasonal bias for hotels and similar establishments was most probably smoothed by overnight business travel.

Residents versus non-residents

Nights spent away by residents in tourist accommodation were more concentrated in July and August than travel by non-residents

Domestic travellers appeared to be the main contributors to the peak in nights spent in tourist accommodation in July and August (see Figure 4). In the other months of the year, the figures for residents and non-residents were comparable.

Schemes to encourage domestic holiday makers to travel in the low season could reduce the seasonal bias in the tourist accommodation sector. However, although the domestic market may be easier to reach (from a marketing and tourism policy point of view), the importance of school holidays and production downtime in certain sectors of the economy cannot be ignored as key factors in planning holidays.

In Figure 4, the number of nights spent away by residents peaked clearly in July and August, and dipped in September. Over a three-month period, the seasonal effects were slightly smoothed by grouping peak months and more 'normal' months.

At aggregate level (EU-27), the distribution of nights spent away by residents and non-resident broadly followed the same pattern (Table 5). In the countries identified earlier as having a strong seasonal bias in the accommodation sector, there were differences between the numbers of resident and foreign guests. In Bulgaria, Denmark, Greece and Croatia, the share of nights spent by residents (out of the total number of nights away during the year) recorded in the third quarter was comparable to the European average, while more than half of all nights spent away by non-residents were recorded in the third quarter. In Italy and France, both the share of nights spent by residents and non-residents was much higher in the third quarter compared to the rest of Europe. In Cyprus, 55% of all nights spent by residents was recorded during the third quarter (but note that the domestic market accounted for only 10% of the Cypriot accommodation sector in 2009).

Relationship with employment

The strong seasonal variation in activity of the accommodation sector was only partially reflected in the quarterly employment figures

We have seen major seasonal fluctuations in the [occupancy](#) (i.e. nights spent away) of accommodation establishments. This final chapter takes a look at the effects of seasonality on employment in the accommodation sector.

Using data from the European [Labour force survey](#), Figure 5 indicates that there was a much stronger seasonal bias in the accommodation sector than in the entire HORECA (hotel, restaurant and catering) sector. In the economy as a whole, seasonal fluctuation was very limited, but this aggregate figure of course hides strong seasonal variations in certain branches of the economy.

Nevertheless, seasonality in employment was much less pronounced than economic output (in terms of nights spent away). In the peak season (third quarter), occupancy in accommodation establishments was 72% higher than the annual average while employment was only 11% higher in this quarter compared to the annual average. Although occupancy was 40% lower in the first quarter than the annual average, employment was only 8% below the annual average. Since the data refers to the number of persons employed, it was not possible to analyse the effect of different working time patterns according to the season.

Data sources and availability

Directive 95/57/EC on the collection of statistical information in the field of tourism organises the [European Statistical System](#) of tourism statistics. This system consists of two main components: statistics on capacity and occupancy of tourist accommodation and statistics on tourism demand. The former are collected in most Member States via surveys filled in by accommodation establishments, while the latter are mostly collected by means of traveller surveys at the border or via traditional household surveys.

Statistics on the occupancy of tourist accommodation refer to the number of arrivals (at accommodation establishments) and the number of nights spent by residents and non-residents, broken down by type of establishment or by region. Both annual and monthly series are available. Statistics on the use of beds ([occupancy rates](#)) are also compiled.

Statistics on the demand for tourism look at participation, i.e. the number of residents that make at least one trip of at least four overnight stays during the reference period (quarter, year). They also look at the number of tourism trips made (and the number of nights spent on those trips), broken down by tourism-related variables such as country of destination, month of departure, length of stay, type of organisation of the trip, mode of transport, type of accommodation or expenditure, and by socio-demographic variables, such as age or gender. Annual and quarterly series are available.

Context

In June 2010, the European Commission released a Communication entitled "[Europe, the world's No 1 tourist destination - a new political framework for tourism in Europe](#)". One of the challenges and opportunities facing the European tourism industry is the seasonal distribution of demand for tourism. Better use of existing tourist infrastructure and staff in the low season could help businesses improve their productivity and benefit from a more stable and motivated workforce. Extending the tourism season or spreading tourism activities more evenly throughout the year can significantly boost the [sustainability](#) and [competitiveness](#) of European tourist destinations.

Seasonality in tourism demand

Data from July 2010, most recent data: Further Eurostat information, Main tables and Database .

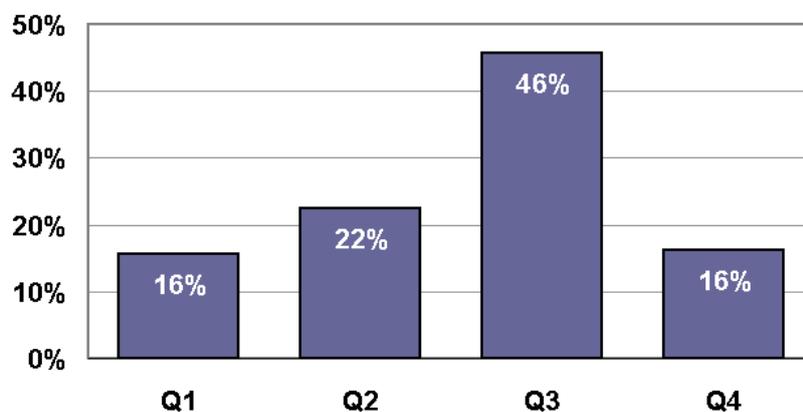

This article focuses on the seasonal pattern of tourism demand in the [European Union \(EU\)](#) , participation in tourism by EU residents, the trips they made and the number of [nights spent](#) on those trips. Tourism demand includes all trips made, regardless of whether they were spent in [tourist accommodation](#) (such as [hotels](#) or [camp-sites](#)) or in less formal and often unpaid types of accommodation (such as owned dwellings or accommodation provided for free by friends or relatives).

This analysis from the point of view of the *demand* side complements another article on [seasonality in the tourist accommodation sector](#) in which the seasonal bias in the *supply* by the tourist accommodation sector is discussed.

Main statistical findings

Overall seasonal pattern

Europeans take 46% of their holidays in the third quarter of the year

In 2009, tourism demand was concentrated in the third quarter, with more than one in three holiday trips made in July, August or September. When taking into account the duration of the trips, the seasonal pattern was even more pronounced, with EU residents spending 46% of all nights away on holiday in the third quarter of 2009. Short holiday trips, domestic holidays and business trips tended to smoothen the seasonality of tourism demand. The increasing popularity of short trips slightly reduced the seasonal bias in the period 2004-2009.

Proportion of population on holiday

Almost half of the EU population went on holiday in the 3rd quarter of 2009

During the third quarter of 2009, nearly half (48%) of all EU residents went on holiday at least once with at least one overnight stay (see Table 1). During the other three quarters of the year, far fewer EU residents went on holiday, ranging from around one in four to one in three persons. In all countries, the period July-September was the most popular time to go on holiday. The biggest infra-annual variation was observed in Cyprus, where 83% of the population went on holiday in the third quarter of 2009 and only 16% or less travelled at other times of the year.

When looking at holidays of at least 4 nights, the share of the population that travelled during the third quarter (35%) was almost double that during the second quarter (19%). During the first and fourth quarter of 2009, only 13% of the population went on holiday for at least 4 nights.

Length of holidays

More than one in three holidays took place during the third quarter. In terms of nights spent away, 46% were in the third quarter of 2009, with an even stronger bias for long trips

While the previous section focused on participation in tourism, i.e. the share of the population that went on holiday at least once during the reference quarter, this section takes a closer look at the time people spend on holiday and the number of nights they spent away.

The number of trips made by EU residents in the first and the last quarter of 2009 were both around 20% of the total number of annual trips (see Figure 1a and the left part of Table 2). With some differences, this conclusion holds for all Member States. Only in Cyprus did the first and last quarter account for less than 10% of trips. In the second quarter — largely overlapping with the spring and in many countries with Easter — a slightly higher number of trips was recorded compared to the first and last quarter. On average across the EU, 26% of holidays were taken in this quarter. Unsurprisingly, the third quarter was the most popular period for going on holiday. More than one in three (34%) holiday trips in 2009 was made in July, August or September. When looking at the highest average absolute difference between the four quarterly figures and the average over the quarters, the strongest seasonal pattern in tourism demand was observed in Cyprus, where 70% of all holiday trips were made in the third quarter. This quarter was also particularly popular for Greek and Slovenian tourists (both 45%) and for Italian and Bulgarian tourists (both 43%). The least pronounced seasonal pattern was recorded for German tourists, who showed the most equal spread over the four quarters of the year: 21%, 25%, 29% and 25%. Residents of Ireland, Sweden, Finland and Spain also tended to spread their holiday trips over the year more evenly.

An analysis of the seasonal pattern of the number of nights spent on holiday — in other words the length of trips — shows a similar but more pronounced distribution (see Figure 1b and the right part of Table 2). While 34% of all trips were made in the third quarter, the number of nights spent on holiday in the third quarter accounted for 46% of the total in 2009. This means a longer average duration of trips (see Table 3). The average trip made in the first, second and fourth quarter lasted 4 to 5 days (nights), in the third quarter this rose to slightly over a week (7.4 overnight stays for holidays taken by EU residents).

Only one Member State recorded more than half of its holiday trips during the third quarter (Cyprus, 70%), but residents of eight Member States spent more than half of their holiday nights away during the third quarter. The highest seasonal peak in terms of the third quarter's share in nights spent on holiday was observed in Greece (67%), Italy (63%) and Slovenia (59%). Again, the seasonal pattern was less pronounced in the quarterly number of nights spent away by German, Swedish and Finnish tourists. Unsurprisingly, the latter two countries also recorded the highest number of holiday trips per person (7 trips per year in Finland, 5 trips per year in Sweden). In other words, and as one could expect, more trips per person resulted in a more even spread of the trips throughout the year.

When looking at the breakdown by duration of trips (see Figures 2 and Table 4), short trips of 1 to 3 overnight stays were distributed more evenly over the year compared to longer trips of at least 4 overnight stays. Contrary to the general conclusions above, the second quarter was the most popular for taking short trips (28% of all short holiday trips on average for the EU, compared to 27% for the third quarter).

In 9 Member States, short holiday trips in "spring" outnumbered short trips in the main summer season. French, Dutch and Portuguese tourists made more than 30% of their short holiday trips in the second quarter. Again, Cyprus showed the strongest seasonal bias with 85% of short trips taken in July, August and September. However, for long holiday trips, 44% of the annual number of long trips made by EU residents was taken in the third quarter, by far the preferred season for making long trips. In all countries, the third quarter was the top season for going on holiday. In 8 EU Member States, at least half of long holiday trips were taken in the third quarter, rising to 60% or more in Greece and Slovenia.

Domestic versus abroad

Only in the third quarter, the share of trips abroad exceeded 25% of the total

In 2009, EU residents made over 790 000 holiday trips in their own Member States (domestic holiday trips) and nearly 245 000 holiday trips abroad (see Table 5). The spread of domestic and trips abroad over the four quarters of the year is relatively comparable, with a slightly stronger seasonal pattern for trips abroad (see Figures 3a and 3b). The number of domestic holidays taken during the peak quarter (the third quarter) exceeded the number taken in the trough quarter (the first quarter) by 78% and the number of holiday trips abroad more than doubled in the peak quarter compared to the trough quarter.

On average over the year, holidays abroad accounted for 23.7% of all holiday trips. At quarterly level, the share exceeded 25% only in the third quarter (see Figure 3c).

People tended to take longer holidays during the third quarter (see also Table 3), due most likely to periods of annual leave or school holidays. Given the fixed costs of transportation, it is unsurprising that the season during which trips were the longest is also the most popular season for going on trips abroad.

Holiday patterns in Europe differed widely in 2009. In a number of countries, the number of trips during the peak season was more than twice the number of trips in the trough quarter, both for domestic and foreign trips. This was the case in Greece, Italy, the Netherlands and Poland. In other countries, such as Ireland, Finland, Sweden and (to a lesser extent) Germany, the seasonal bias was relatively small for both types of destination.

In a group of countries, the seasonal pattern for domestic trips was low compared to other countries but there were strong seasonal fluctuations for trips abroad made by residents. This was especially so in Romania, Slovenia and Slovakia, but also in the Czech Republic and Austria, the difference between the third and the first quarter was twice as high for trips abroad than for domestic trips. The opposite happened in Estonia and Croatia, where the pattern of holidays abroad was relatively evenly spread across the year but fluctuated more for domestic holiday trips.

The data do not show a link between the importance of tourism abroad and seasonality of this type of holiday. For nearly all countries where trips abroad accounted for 10% or less of the total number of holiday trips made in 2009 (Bulgaria, Greece, Spain, France, Portugal and Romania) the seasonal pattern of trips abroad did not differ much from the EU average. The only exception was Romania, where half of all holiday trips abroad were made during the third quarter (the second highest figure in the EU, after Slovenia).

Business trips

Business trips showed a less pronounced seasonal pattern and tended to partly compensate for the peak and trough periods

Although reliable statistics on business trips broken down by quarter are not available for all Member States, Figures 4a and 4b give an illustration at aggregate level of the 27 Member States of the European Union. Business trips were spread more evenly over the year than holiday trips, with a seasonal variation ranging from just over 43 million business trips in the third quarter, or 23% of the annual total, to just under 48 million business trips in the second quarter, or 26% of the annual total (EU-27 data, excluding the Netherlands and Malta).

On average over the year, business trips represented around 15% of all trips made by EU residents. As shown in Figure 3b, this figure ranged from around 20% in the first and last quarter of the year to 11% in the main holiday period, the third quarter.

Evolution over time

In the period 2004-2009, the seasonality of demand for tourism by EU residents fell slightly

Based on data available on 21 Member States for 2004 and 2009, this section takes a look at the trend in recent years of the seasonal bias in tourism demand for non-professional purpose. Although the period spans only six reference years, some patterns do emerge.

In all four quarters, both the number of holiday trips and the number of nights spent away increased in 2009 compared to the same quarter in 2004 (see Figures 5a and 6a).

However, two important trends are noticeable.

Firstly, the number of trips increased at a faster pace than the number of nights away, leading to a shorter average length of trip. This phenomenon is apparent all year round.

Secondly, the increases were significantly higher during the traditional low season compared to the peak season. In the first and fourth quarter, the number of trips increased by 19% and 21% between 2004 and 2009, while in the second and third quarter the increase was 14% and 13%. A broadly similar pattern was observed in the increase in nights spent away during the same quarter in this period, with an increase of 14%, 10%, 3% and 7% in the first, second, third and fourth quarter.

Between 2004 and 2009, Europeans slightly changed their tourism behaviour and tended to take additional holidays during the traditional low season rather than in the peak season. Given the reduction in the average length of trips, these additional trips tended to be shorter. The statistics on participation in tourism (not shown in the Figures) also indicated an increase between 2004 and 2009 in the number of persons who went on holiday at least once in the first or the fourth quarter, compared to the second or third quarter.

The relatively stronger demand for tourism during the low season (first and fourth quarter) led to a reduction in seasonal variation, as shown in the quarterly distribution of holiday trips and nights in Figures 5b and 6b. The share of the first quarter in the total number of holiday trips increased by 0.5 percentage points between 2004 and 2009 while the share of the third quarter dropped by 0.8 percentage points. The number of nights spent away increased by 0.9 percentage points in the first quarter and fell by 1.7 percentage points in the third quarter.

Data sources and availability

[Directive 95/57/EC](#) on the collection of statistical information in the field of tourism organises the [European Statistical System](#) of tourism statistics. This system consists of two main components: statistics on capacity and occupancy of tourist accommodation and statistics on tourism demand. The former are collected in most Member States via surveys filled in by accommodation establishments, while the latter are mostly collected by means of traveller surveys at the border or via traditional [household](#) surveys.

Statistics on the [occupancy](#) of tourist accommodation refer to the number of arrivals (at accommodation establishments) and the number of nights spent by residents and non-residents, broken down by type of establishment or by region. Both annual and monthly series are available. Statistics on the use of beds ([occupancy rates](#)) are also compiled.

Statistics on the demand for tourism look at participation, i.e. the number of residents that make at least one trip of at least four overnight stays during the reference period (quarter, year). They also look at the number of tourism trips made (and the number of nights spent on those trips), broken down by tourism-related variables such as country of destination, month of departure, length of stay, type of organisation of the trip, mode of transport, type of accommodation or expenditure, and by socio-demographic variables, such as age or

gender. Annual and quarterly series are available. This article is based on the data on tourism demand.

Context

In June 2010, the [European Commission](#) released a Communication entitled "[Europe, the world's No 1 tourist destination - a new political framework for tourism in Europe](#)". One of the challenges and opportunities facing the European tourism industry is the seasonal distribution of demand for tourism. Better use of existing tourist infrastructure and staff in the low season could help businesses improve their productivity and benefit from a more stable and motivated workforce. Extending the tourism season or spreading tourism activities more evenly throughout the year can significantly boost the [sustainability](#) and [competitiveness](#) of European tourist destinations.

Occupancy rates in hotels and similar establishments

Data from January 2013. Most recent data: Further Eurostat information, Main tables and Database .

This article focuses on the short-term evolutions in the occupancy of bedrooms and bed places of hotels and similar accommodation establishments in the European Union (EU) .

With the adoption of Regulation 692/2011 concerning European statistics on tourism, information on occupancy of hotels and similar establishments has significantly improved. From 2012 onwards, Member States transmit to Eurostat monthly data on net occupancy rate of bedrooms . This is a new variable complementing already existing information on net occupancy rate of bed places .

This article is the first publication of September 2012 data on occupancy rates of bedrooms and bed places.

Note: No data available for BG, IE, EL, and IT.

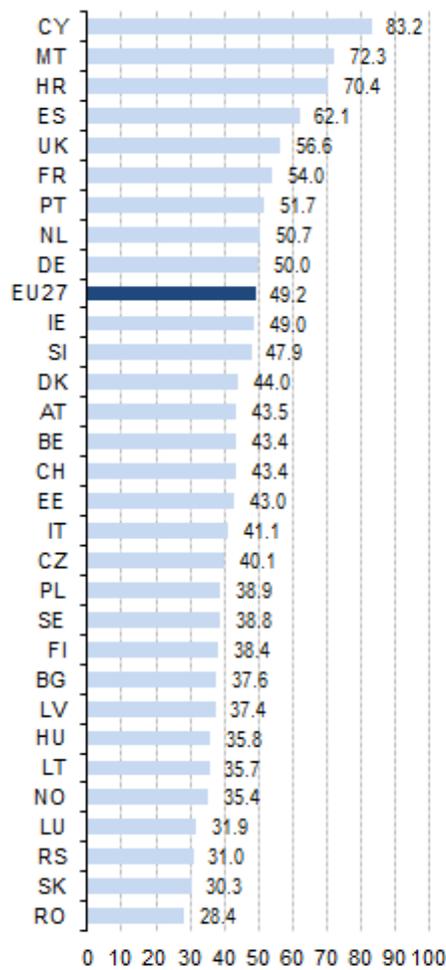

Source : Eurostat (online data code: tour_occ_nor_br)

⁽¹⁾ EU-27 estimate made for the purpose of this publication.

⁽²⁾ BG 2011: Only quarterly data available.

Source: Eurostat (online data code: tour_occ_nor_bp, tour_occ_nim)

Table 2: Net occupancy rates of bed places in hotels and similar establishments, January to September 2012 compared with the previous year - Source: Eurostat (tour_occ_nor_bp) (tour_occ_nim)

Main statistical findings

Occupancy rates of bedrooms

Data on occupancy rates of bedrooms is available since January 2012 when the new regulation entered into force. Consequently, the comparison with the previous year is not yet possible.

In September 2012, occupancy rates of bedrooms in hotels and similar establishments of EU Member States where data is available ranged from 31.8% in Luxembourg to 82.3% in Malta. More than 80% of the available bedrooms in Malta and Cyprus have been in use during this month (see Figure 1 and Table 1).

Occupancy rates of bed places

Data on occupancy rates of bed places for the most recent [reference month](#) available are compared with the same month of the previous year. In addition - and to smoothen fluctuations - data from January to the most recent available month of the current year are compared with the same period one year earlier.

Compared with September 2011, net occupancy rates of bed places in the European Union decreased by 1.0 percentage point in September 2012 (see Table 2). These rates ranged from 28.4% in Romania to 83.2% in Cyprus (see Figure 2).

Looking at the nine months' period from January to September 2012, net occupancy rates of bed places in the EU recorded a decrease (-0.6 percentage points) compared with the same period of the previous year (see Table 2). With 68.8%, 59.9% and 56.4% respectively, Cyprus, Malta and Spain were the three Member States with the highest occupancy rates during this period.

Data sources and availability

Data on arrivals for the same reference period are available in Eurobase . For more recent data on nights spent, see [Nights spent in tourist accommodation establishments](#) .

Symbols ":" data unavailable or unreliable

Context

The EU is a major tourist destination, with six Member States among the world's top ten destinations for holidaymakers. Tourism is an important activity in the EU which has the potential to contribute towards employment and economic growth, as well as to development in rural, peripheral or less-developed areas. These characteristics drive the demand for reliable and harmonised statistics within this field, as well as within the wider context of regional policy and sustainable development policy areas.

Tourism statistics at regional level

Data from February 2012. Most recent data: Further Eurostat information, Main tables and Database .

This article presents regional patterns of [tourism](#) in the [European Union \(EU\)](#) for 2010; its main focus is tourism [occupancy](#) within [tourist accommodation establishments](#) , while it also presents figures on the capacity of tourist accommodation across EU regions. The number of [overnight stays](#) , which reflects both the length of stay and the number of visitors, is considered a key indicator for accommodation statistics.

[Coastal regions](#) are very important for tourism in many EU Member States. An article dedicated to [coastal regions](#) , provides a specific focus on tourism and on transport.

Main statistical findings

According to the [United Nations World Tourism Organisation](#), Europe is the most frequently visited region in the world. In 2009, 5 of the top 10 countries for visitors in the world were EU Member States. The wealth of European cultures, the variety of its landscapes and the exceptional quality of its tourist infrastructure are likely to be among many of the reasons why tourists choose to take their holidays in Europe.

Number of overnight stays

There were 2233 million nights spent in [hotels](#), [campsites and other collective accommodation establishments](#) (the latter includes tourist dwellings) across the EU-27 in 2009, of which 1331 million were by domestic tourists in their own country of residence.

Map 1 gives an overview of the number of overnight stays by residents and non-residents (combined) in 2010. Tourism in the EU is often concentrated in coastal regions, although the Alpine regions and some cities also experience high demand. A total of 54 regions (and Ireland for which no regional analysis is available) in the EU-27 recorded more than 10 million nights spent in hotels, campsites and other collective accommodation establishments, among which 20 regions recorded more than 24 million nights. This top 20 list included six regions in Italy, five each in Spain and France, two in Germany and one each in Austria and the United Kingdom; note that Ireland as a whole recorded 33.7 million overnight stays.

The top 20 tourist regions (excluding Ireland) are shown in Figure 1, with an analysis between the different types of accommodation. These 20 regions together accounted for 38.3% of all overnight stays in the 270 regions of the EU-27 for which data are available. The Spanish island region of the Canarias and the French capital city region of Île-de-France had by far the highest numbers of overnight stays, 79.1 million and 74.0 million respectively. They were followed by the Spanish region of Cataluña which includes Barcelona, the Costa Brava and Costa Dorada (65.1 million); the Italian region of Veneto which includes Venice (60.8 million); and another Spanish region, the Illes Balears, which includes the main island destinations of Mallorca, Menorca, Eivissa (Ibiza) and Formentera (58.2 million). Almost one in seven tourism nights spent in the EU was spent in one of these five regions. Inner London in the United Kingdom (eighth place), Tirol in Austria (16th place) and the German regions of Oberbayern (18th place) and Mecklenburg-Vorpommern (20th place), were the only regions in the top 20 that were not in one of the three leading tourism Member States. Jadranska Hrvatska (Croatia) recorded 34.9 million overnight stays in 2010, which was between the levels recorded by the regions ranked 12th and 13th in the EU.

In 14 of the top 20 regions in the EU, more than half of the nights were spent in hotels and similar establishments. The regions with the largest number of overnight stays in hotels in 2010 were the capital city regions of the Île de France and Inner London, alongside the Spanish regions of the Canarias, Illes Balears, Cataluña and Andalucía, all with more than 40 million overnight stays; the top 20 region with the highest proportion of nights spent in hotels was Tirol in Austria (91.2%). Among the six remaining top 20 regions (four southern French regions, Veneto in Italy and Mecklenburg-Vorpommern in Germany) a majority of the nights spent by tourists were in campsites and other types of collective accommodation. Overall, the regions with the highest number of overnight stays on campsites were the French regions of Languedoc-Roussillon, Aquitaine, Provence-Alpes-Côte d'Azur and the Pays de la Loire (the latter was not one of the top 20 regions), as well as Veneto in Italy and Cataluña in Spain, all with more than 10 million overnight stays on campsites; note that Jadranska Hrvatska (Croatia) also recorded more than 10 million overnight stays on campsites. The top two tourist regions for other collective accommodation establishments were the Canarias (Spain) and Rhône-Alpes (France), both with more than 20 million overnight stays.

Recent trends in tourism

Maps 2 and 3 show the annual average rate of change in the number of nights spent in hotels and on campsites during the period 2007–10. In the EU-27, this measure of tourism showed an average fall of 2.2% per year for hotels and a rise of 2.3% per year for campsites. It is likely that the different developments observed for hotels and campsites can be linked to the financial and economic crisis, and the substitution of nights spent in hotels by nights spent in campsites may have been in order to lower the cost of a holiday.

Concerning hotels, this measure of tourism fell in 145 (of the 268 regions with data available), with average reductions of 4% or more per annum in 47 regions and losses of 10% or more in nine regions. Several of the regions with large falls were in France, Romania and the United Kingdom with the largest reduction (-16.5% per annum) in the French region of Guadeloupe. Among the regions in the [EFTA](#) countries, the largest fall was -4.9% per annum in the Norwegian region of Hedmark og Oppland. All four regions in Croatia and the former Yugoslav Republic of Macedonia recorded a reduction in their respective number of nights spent in hotels, but the Croatian region of Središnja i Istocna (Panonska) Hrvatska was the only one to record an average decline in excess of 5% per annum.

By contrast, 54 regions in the EU recorded an annual average increase in excess of 2%, among which 16 recorded average growth above 5% per annum, but only the Dutch region of Flevoland recorded growth in excess of 10%. Six of the regions with average growth above 5% were in Poland and three each in Belgium and Germany, two in the United Kingdom, and one each in Italy and the Netherlands.

Camping

A more varied development could be seen for campsites (see Map 3), with a much wider range in the rates of change between 2007 and 2010. The number of nights spent on campsites fell by an average of 8% or more per annum in 47 of the 248 regions for which data are available; among these there were reductions of 20% or more per annum in 17 regions, with the largest decline recorded for the Bulgarian region of Yugoiztochen (-52.3% per annum). The regions where the number of nights spent in campsites fell by 20% or more per year were spread across eight Member States, but included several capital city regions, notably those in the Czech Republic, Spain and Slovakia. By contrast, 47 regions recorded an annual average increase in excess of 4%, among which 20 regions posted growth averaging more than 10% per annum. The fastest average growth was also recorded in Bulgaria, 129.8% in the region of Severozapaden; this high growth rate was recorded from a very low number of nights spent on campsites. Four of the regions with average growth above 10% were in Poland, three each in Germany, Greece and the United Kingdom, two in Bulgaria and one each in Belgium, Cyprus, Spain, Italy and the Netherlands.

In the regions of western Europe (mainly coastal), particularly in Scandinavian countries, campsites were more frequently used as tourist accommodation than in central and eastern Europe. Taking an average across the 257 regions of the EU-27 for which data are available, around one in six of all overnight stays were spent on campsites, with the remaining five out of six in hotels and other collective accommodation establishments. Map 4 shows significant disparities in the regional share of camping: regions with campsites accounting for more than 30% of the total nights spent in hotels, campsites and other collective accommodation establishments were concentrated in the United Kingdom (10 regions), France (nine regions), Sweden (five out of eight Swedish regions), Denmark (four out of five Danish regions), the Netherlands and Portugal (two regions each) and Italy and Luxembourg (one region each). Furthermore, five of the seven Norwegian regions reported that more than 30% of the tourist nights spent in hotels, campsites and other collective accommodation establishments were on campsites, as was the case in one of the Croatian regions.

No regions in Bulgaria, Estonia, Latvia, Lithuania, Poland, Romania or Slovakia had a share of nights spent on campsites above 5%. With the exception of Luxembourg (analysis based on the whole country at [NUTS](#) level 2) where the share of nights spent on campsites reached 32.8% in 2009, the likelihood of spending the night on a campsite was generally low in capital city regions. Only in the capital city regions of the Netherlands, Slovenia, Denmark and Portugal, all of which are coastal regions, did this share exceed 10% (but was under 14%); in 16 of the Member States the share of nights spent on campsites was under 5% in the capital city regions.

Share of inbound tourism

For the EU-27 as a whole, non-residents accounted for 40.4% of all overnight stays in hotels, campsites and other collective accommodation establishments in 2009. Across the regions of the EU in 2010, the share of inbound tourism (visits from abroad) differed very widely, ranging from a low of 3.1% of the total nights spent in the Romanian region of Sud-Vest Oltenia to a high of 95.3% of all nights spent in Malta. Foreign overnight visitors also accounted for more than 90% of overnight stays in Luxembourg, the Greek region of Kriti, the Czech capital city region of Praha, and Cyprus; this level was also exceeded in Liechtenstein and the Croatian region of Jadranska Hrvatska.

Map 5 shows overnight stays by foreign visitors as a percentage of total overnight stays. In total there were 48 EU regions where more than half of the overnight stays in 2010 were made by non-residents. This was often the case in capital city regions — the only exceptions being Germany, Spain, Finland, Sweden and Poland; no data are available for Ireland. Southern Europe's island and coastal regions recorded particularly high shares of overnight stays by foreign visitors, especially Malta, Cyprus, the Greek island regions, the Spanish Illes Balears and Canarias, the Spanish region of Cataluña, the Portuguese Região Autónoma da Madeira, the Portuguese region of the Algarve, the Bulgarian Black Sea coast and the Italian region of Veneto. Alpine regions in Austria and Italy also recorded a majority of their overnight stays being made by foreign visitors, as did many regions in Belgium, Greater Manchester in the United Kingdom, the Finnish island region of Åland, and Severozápad in the Czech Republic (which includes the spa city of Karlovy Vary).

Top 20 tourist regions in the EU-27 visited by foreign tourists

Figure 2 shows the top 20 EU regions recording the highest number of overnight stays by foreign (inbound) tourists in 2010. These top 20 regions accounted for more than half of all overnight stays by non-residents across the EU-27. The top six regions visited by foreign tourists (Canarias, Illes Balears, Inner London, Cataluña, Île-de-France and Veneto) collectively recorded more overnight stays than the next 14 regions put together. The list of the top 20 tourist regions visited by foreign tourists includes regions in eight different Member States: Spain, the United Kingdom, France, Italy, Austria, Greece, Cyprus and the Netherlands: five of the regions were Spanish and five were Italian. The Croatian region of Jadranska Hrvatska had 32.1 million overnight stays from non-residents, which placed it between the sixth and seventh most popular regions within the EU (by this measure).

Most popular regions

Across the whole of the EU-27 in 2009, the most popular region for residents to visit was the capital city region of France (Île de France) with almost 30 million nights spent by domestic tourists — this increased to 36 million nights in 2010. The most popular destinations for non-residents were the Spanish island regions of the Canarias and Illes Balears, where almost 61 million nights and just over 48 million nights, respectively, were spent by foreign tourists in 2009; this increased to 65 million and 51 million in 2010.

Table 1 shows by country, separately for residents and non-residents which region had the most number of overnight stays in hotels, campsites and other collective accommodation establishments in 2010. Tourists often visit regions with a coastline and this is, by definition, the case for the nine Member States where all NUTS level 2 regions have a coastline; equally this was not the case for the five Member States that are landlocked.

Of the remaining 13 Member States (that were neither landlocked nor completely coastal) the most visited region was generally different for residents and for non-residents, the only exceptions being the Black Sea coastal region of Yugoiztochen (Bulgaria), the Île de France (which includes Paris, France) and Etelä-Suomi (which includes Helsinki, Finland). Among residents, the most popular region had a coastline in 10 of these 13 Member States, the exceptions being in France, the Netherlands and Slovenia. Among non-residents, the situation was more balanced, with the most visited region having a coastline in seven of the 13 Member States; in five of the most popular regions for non-residents that did not have a coastline the most popular region was the capital city region, the only exception being Poland where the region of Malopolskie (including the city of Kraków) was the most popular for non-residents.

Among the nine Member States where all NUTS level 2 regions have a coastline, there were only four countries with more than one region. Of these, non-residents were most likely to visit the capital city regions in Denmark and Sweden, while in Portugal they were more likely to visit the Algarve; for Ireland information is not available for non-residents.

Among the four landlocked Member States with more than one region (therefore excluding Luxembourg) the most popular regions were a mixture of capital city regions (for non-residents visiting the Czech Republic or Hungary) and regions with mountains, lakes and historic towns and cities.

Tourism intensity

Map 6 provides a measure of **tourism intensity** (also called carrying capacity): it measures the number of overnight stays in relation to the resident population. This serves as an indicator of the relative importance of tourism for a region. It provides a more nuanced guide to the economic significance of tourism for a region than the absolute number of overnight stays. Furthermore, in the context of the sustainability of tourism, it can also be seen as an indicator of possible tourism pressure. The average tourism intensity in the EU-27 was 4463 overnight stays per 1000 inhabitants in 2009.

The huge importance of tourism to many of the EU's coastal regions and, even more so, to its islands and most of the Alpine region, is clear from Map 6. A total of 30 EU regions recorded a tourism intensity of more than 10000 overnight stays (in hotels, campsites or other collective tourist accommodation) per 1000 inhabitants (data are generally available for 2010): six were in the United Kingdom (data are for 2009), five in Italy, four in Austria, three in Greece, two each in Germany, Spain, the Netherlands and Portugal, and one each in Cyprus, Finland, France (2009) and Malta. From a geographical perspective, seven of these regions were Alpine and 20 of them had a coastline; the three regions that were neither Alpine nor had a coastline were the German region of Trier, the Dutch region of Drenthe and Inner London in the United Kingdom.

The Italian Provincia Autonoma Bolzano/Bozen had the highest tourism intensity, with 56519 overnight stays per 1000 inhabitants in 2010, followed by the Spanish region of Illes Balears and the Greek region of Notio Aigaio, both with more than 50000 overnight stays per 1000 inhabitants.

Among the regions within Iceland, Liechtenstein, Norway (2009) and Switzerland, the mountainous Norwegian region of Hedmark og Oppland had the highest tourism intensity, with 11505 overnight stays per 1000 inhabitants; the only other mountainous region with in excess of 10000 overnight stays per 1000 inhabitants was Ticino (Switzerland). The Croatian coastal region of Jadranska Hrvatska recorded 23784 overnight stays per 1000 inhabitants, which was a slightly higher intensity than the 13th ranked region within the EU.

By contrast, at the other end of the ranking there were 71 regions with 2000 or fewer overnight stays per 1000 inhabitants, of which 22 had 1000 or fewer overnight stays per 1000 inhabitants. Most of the latter were located in Poland (8 regions), Romania (6 regions), Bulgaria (3 regions) or Belgium (2 regions, 2009). Apart from Jadranska Hrvatska, the remaining two Croatian regions as well as the former Yugoslav Republic of Macedonia also recorded a level of intensity below 1000 overnight stays per 1000 inhabitants.

Average length of stay

Map 7 shows the **average length of stay** in hotels, campsites and other collective tourist accommodation in 2010. The total number of nights spent in a region is influenced by the number of visitors and their average length of stay. The importance of each of these two factors depends on the nature of the region. For example, urban regions frequently have very large numbers of visitors, but they tend to stay for only a few days. A large proportion of visitors to these regions are often there for professional reasons, but tourists staying for private reasons also tend to opt for relatively short stays. By contrast, the average length of stays was substantially longer in typical holiday regions visited chiefly for recreational purposes. Note that the data presented refers to the average duration of stay at a particular establishment and as such does not necessarily reflect the duration of stay in a particular region, as it is possible that tourists move from one establishment to another, staying at different hotels or campsites within the same region when they are touring around a specific area.

There were 56 NUTS level 2 regions within the EU that reported an average length of stay in hotels, campsites and other collective tourist accommodation of more than 3.5 nights in 2010. The highest figures were recorded in Spanish and Greek holiday destinations: with the top five regions including the Canarias (7.5 nights), Kriti (6.7 nights), the Illes Balears (6.6 nights) and Notio Aigaio and Ionia Nisia (both 6.3 nights).

The highest average numbers of nights spent in campsites were observed mainly in coastal regions, while for hotels the longest average stays were mainly in island regions. Overall, visitors tended to stay longer in campsites than in hotels: for the EU-27 as a whole the average length of stay in campsites was 4.9 nights in 2010 (excluding Ireland, Luxembourg and Malta) compared with 2.5 nights for hotels (excluding Ireland and Luxembourg).

Accommodation capacity

In the EU-27 there were more than 200000 hotels and in excess of 27000 tourist campsites in 2010; together these provided 12.5 million bed places in hotels and around 9.4 million places on tourist campsites; a further 5.6 million bed places (2009 data) were available in other collective accommodation establishments, including tourism dwellings.

Eight NUTS level 3 regions within the EU offer more than 100000 bed places in hotels: three in Spain (Mallorca, Barcelona and Madrid), three in Italy (Bolzano/Bozen, Rimini and Roma), one in France (Paris) and one in Greece (Dodekanisos). Map 8 gives an overview of the number of bed places in hotels in 2010. Regions with a high number of bed places in hotels are, unsurprisingly, often the same regions that recorded a high number of overnight stays. They were mainly concentrated around coastal, mountainous and lake regions as well as in regions with capital and other major cities.

Nine out of the top 20 EU regions (NUTS level 3) ranked according to their accommodation capacity in 2010 were in France, while five each were in Spain and Italy and one in the United Kingdom. Figure 3 shows these top 20 regions with an analysis by type of accommodation. With the exceptions of Paris, and to a lesser extent Savoie, the French regions in this list offered mainly accommodation on campsites, while the Italian regions had a higher share of their capacity located in hotels (with the exception of Venezia). The Spanish regions were more diverse with hotels dominating accommodation capacity on Mallorca, campsites providing more than half of the accommodation capacity in Girona (Costa Brava), and other collective accommodation (for example, tourist dwellings available for rent) reaching close to 40% in Alicante/Alacant.

Data sources and availability

Harmonised statistical data on tourism have been collected since 1996 in the EU Member States on the basis of Council Directive 95/57/EC of 23 November 1995 on the collection of statistical information in the field of tourism. The programme covers both the supply side, for example through data on available accommodation capacity (establishments, rooms and bed places) and its occupancy (number of visitor arrivals and overnight stays), and the demand side, such as the travel behaviour of the population. Regional results are available only for the supply side.

The statistical definition of tourism is broader than the common, everyday definition. It encompasses not only private trips but also business trips. This is primarily because it views tourism from an economic perspective. Private visitors and business visitors have broadly similar consumption patterns. They both make significant demands on transport, accommodation and restaurant services. To providers of these services, it is of secondary interest whether their customers are private tourists or on business. Tourism promotion departments are keen to combine both aspects by emphasising the attractiveness of conference locations as tourist destinations in their own right and feature these services in marketing activities.

Note that previous articles on regional tourism statistics focused on hotels and campsites; recent improvements in data availability have made it possible to extend the coverage in this article so as to include other collective accommodation establishments too.

Context

Tourism diversity

The ongoing enlargement process within the EU has enriched tourism potential by the increased cultural diversity. Tourism is particularly significant in remote regions which are far from the economic centres of their country, where tourism-related services are often a prominent factor in securing employment and are one of the main sources of income for the local population. This applies especially to Europe's island states and regions, to many coastal regions (see also the article on coastal regions), particularly in southern Europe, and to the whole of the Alpine region.

Tourism is an important activity with social, cultural and environmental implications, involving large numbers of small and medium-sized enterprises. Its contribution to growth and employment varies widely from one region of the EU to another.

Tourism cuts across many activities: services to tourists include hotels and other accommodation, gastronomy (for example, restaurants or cafés), transport operators, and a wide range of cultural and recreational facilities (for example, theatres, museums, leisure parks or swimming pools). In many regions geared to tourism, retail and other services sectors also benefit considerably from the additional demand generated by tourists.

Inbound tourism is of particular interest to analyses of tourism in a given region. The statistically important factor here is the usual place of residence of the visitors, not their nationality. Foreign visitors, particularly from far-away countries, usually spend more per day than domestic visitors during their trips and thus generate greater demand in the host economy. This expenditure also contributes to the balance of payments of the country visited, and so impacts on the trade deficit or surplus.

Tourism policy

The role that tourism plays in generating growth and jobs and its impact on other policy areas ranging from regional policy, diversification of rural economies, maritime policy, sustainability and competitiveness to social policy and inclusion (tourism for all) are widely acknowledged. Tourism is reflected in national and EU policies: the [Lisbon Treaty](#) acknowledged the importance of tourism, outlining a specific competence for the EU in this field. The communication ' [Europe, the world's No. 1 tourist destination — a new political framework for tourism in Europe](#) ' (COM(2010) 352) was adopted in June 2010. Through this, the [European Commission](#) encouraged a coordinated approach for initiatives linked to tourism and defined a new framework for action to increase the competitiveness of tourism and its capacity for sustainable growth. It proposed a number of European or multinational initiatives — including a consolidation of the socioeconomic knowledge base for tourism. Globalisation of tourism opens up new opportunities, with tourists from new markets able to afford high-value vacations: the European Commission works together with the Member States and other tourism stakeholders on projects such as the [European tourist destinations portal](#) and [European destinations of excellence \(EDEN\)](#) in order to improve the visibility and sustainability of tourism. Another initiative concerns promoting tourism at times of the year that are traditionally regarded as the low season. This pilot initiative, called the [50000 tourists initiative](#) , aims to make use of spare capacity in transport networks and tourist infrastructure.

This article provides information on recent statistics in relation to [tourism](#) in the [European Union \(EU\)](#) . Tourism plays an important role in the EU because of its economic and employment potential, as well as its social and environmental implications. Tourism statistics are not only used to monitor the EU's tourism policies but also its regional and [sustainable development](#) policies.

The role played by tourism, for both businesses and citizens, has grown considerably in recent decades. According to estimates from the [European Commission's Directorate-General for Enterprise and Industry](#) , tourism accounts for more than 5% of the EU-27's [gross domestic product \(GDP\)](#) . The tourist accommodation sector employs 2.4 million people in the EU-27, and total [employment](#) within the whole of the EU-27's tourism industry is estimated to be between 12 million and 14 million people (according to preliminary estimates from [tourism satellite accounts](#)) .

Main statistical findings

Tourism volume – demand and supply

Residents (aged 15 and above) from within the EU-27 made 1055 million holiday trips in 2011. **Short trips** (of one to three nights) accounted for slightly more than half (55.0%) of the total trips made (see Table 1), while approximately three quarters (76.3%) of all trips made were to domestic destinations, with the remainder abroad.

In some EU Member States, over half the total number of holidays trips were to destinations abroad; this was the case for Luxembourg, Belgium, Slovenia and the Netherlands. However, less than 10% of holiday trips taken by residents of Romania, Spain, Greece and Portugal were abroad. These figures appear to be influenced by both the size of the Member State and its geographical location (smaller and more northerly countries tended to report a higher propensity for their residents to take holidays abroad).

It is estimated that some 51.9% of the EU-27's population took part in tourism in 2011, in other words made at least one **trip of at least four overnight stays** during the year. Again, large differences can be observed between the EU Member States, as this participation rate ranged from 6.4% in Bulgaria to 90.3% in Cyprus (see Table 2).

From the supply perspective, it is estimated that just over 202000 **hotels and similar establishments** were active within the EU-27 in 2011; there were nearly 271000 **other collective tourist accommodation establishments** (such as campsites and holiday dwellings). Hotels and similar establishments provided almost 12.6 million **bed places**, of which nearly half (46.4%) were concentrated in three of the EU Member States namely, Italy (2.3 million bed places), Spain (1.8 million bed places) and Germany (1.7 million bed places). In 2011, resident and non-resident (foreign) tourists spent over 1600 million nights in hotels and similar establishments in the EU-27.

Over recent decades, the number of **tourism nights** spent in collective tourist accommodation has generally shown an upward trend (see Figure 1). The start of the period for analysis in Figure 1 is characterised by a relatively low number, in part due to a decline in travel after the 2001 terrorist attacks in the United States. There were also short-term downturns in the number of tourism nights spent in collective tourist accommodation in 2008 and 2009 as a result of the financial and economic crisis: the number of tourism nights in the EU-27 fell by 0.6% in 2008 and by a further 2.8% in 2009. In 2010, however, the number of tourism nights spent in collective tourist accommodation increased by 0.8%. This positive development continued, with growth accelerating to 5.0% in 2011, resulting in 2364 million nights spent in collective tourist accommodation (see Figure 1).

Top holidaymakers travelling abroad

EU-27 residents spent 2263 million nights abroad on holiday (personal travel only) in 2011 (see Table 3). German residents spent 656 million nights during holiday trips outside of Germany in 2011, while residents of the United Kingdom spent 502.9 million nights abroad; residents from these two Member States accounted for more than half (51.2%) of the total number of nights spent abroad by EU-27 residents on holiday.

When taking into account a country's size in terms of its population, Luxembourg was the Member State whose residents spent the most nights abroad per inhabitant (an average of 22.0 nights per annum on holiday in 2011), followed by Cyprus (13.3), Ireland (12.5, data for 2010) and the Netherlands (11.5). At the other end of the spectrum, residents of Romania, Portugal, Greece (data for 2010), Bulgaria, Poland and Italy (2010) spent, on average, less than two nights abroad on holiday in 2011 (see Figure 2).

Top destinations

In 2011, Spain was the most common tourism destination in the EU for non-residents (people coming from abroad), with 239.4 million nights spent in collective tourist accommodation, or almost a quarter (23.2%) of the EU-27 total. Across the EU, the top three most popular destinations for non-residents were Spain, Italy (178.0 million nights) and France (123.0 million nights), which together accounted for 52.5% of the total nights spent by non-residents in the EU-27. The least common destinations were Luxembourg, Lithuania and Latvia; the effect of the size of these Member States should be considered when interpreting these values (see Figure 3 and Table 4).

The number of nights spent (by residents and non-residents) can be put into perspective by making a comparison with the size of each country in population terms, providing an indicator of [tourism intensity](#). In 2011, using this measure, the Mediterranean island destinations of Malta and Cyprus, as well as the alpine and city trip destination of Austria were the most popular tourist destinations in the EU-27 (see Figure 4).

Economic aspects of international travel

The economic importance of international tourism can be measured by looking at the ratio of international travel receipts relative to GDP; these data are from balance of payments statistics and include business travel, as well as travel for pleasure. In 2011, the ratio of travel receipts to GDP was highest in Malta (14.0%) and Cyprus (10.2%), confirming the importance of tourism to these island nations (see Table 5); an even higher ratio was observed in Croatia (14.7%). In absolute terms, the highest international travel receipts in 2011 were recorded in Spain (EUR43026 million) and France (EUR38682 million), followed by Italy, Germany and the United Kingdom.

Germany recorded the highest level of expenditure on international travel, totalling EUR60596 million in 2011, followed by the United Kingdom (EUR36275 million) and France (EUR29922 million). When analysing this expenditure relative to the size of each country in population terms, Luxembourg's residents spent, on average, EUR5289 per inhabitant on travel abroad in 2011, far ahead of the second ranked country, Belgium (EUR1466 per inhabitant), which was followed by Denmark, Ireland, Sweden and Cyprus.

Data sources and availability

Tourism, in a statistical context, refers to the activity of visitors taking a trip to a destination outside their usual environment, for less than a year. It can be for any main purpose, including business, leisure or other personal reasons other than to be employed by a resident person, [household](#) or [enterprise](#) in the place visited. Tourism statistics are currently limited to at least an overnight stay; as of 2014, outbound same-day visits will also be covered by official European statistics.

A system of tourism statistics was established in [Council Directive 95/57/EC](#) of 23 November 1995 on the collection of statistical information in the field of tourism. This legal basis requires EU Member States to provide a regular set of comparable tourism statistics. Amendments in 2004 and 2006 concerned the [enlargement of the EU](#) and recent changes in the world market for tourism. In July 2011 the [European Parliament](#) and the [Council of the European Union](#) adopted a new [Regulation 692/2011](#) concerning European statistics on tourism and repealing Council Directive 95/57/EC; this came into force for the 2012 reference year.

Tourism statistics in the EU consist of two main components: on the one hand, statistics relating to capacity and occupancy in collective tourist accommodation; on the other, statistics relating to tourism demand. In most Member States, the former are collected via surveys filled in by accommodation establishments, while the latter are mainly collected via traveller surveys at border crossings or through household surveys.

Statistics on the capacity of collective tourist accommodation include the number of establishments, the number of bedrooms and the number of bed places. These statistics are available by establishment type or by region and are compiled annually.

Statistics on the occupancy of collective tourist accommodation refer to the number of arrivals (at accommodation establishments) and the number of [nights spent](#) by residents and non-residents, separated into establishment type or region; annual and monthly statistical series are available. In addition, statistics on the use of bed places ([occupancy rates](#)) are compiled.

Statistics on tourism demand refer to tourist participation, in other words, the number of people who made at least one trip of at least four overnight stays during the reference period. There are statistics in relation to the number of tourism trips made (and the number of nights spent on those trips), separated by:

- destination country;

- departure month;
- length of stay;
- type of organisation for the trip;
- transport mode;
- accommodation type;
- expenditure.

The data may also be analysed by socio-demographic explanatory variables, such as age and sex; these statistics are collected on a quarterly and an annual basis.

Data from a range of other official sources may be used to study tourism. These statistics include:

- data on employment in the tourism accommodation sector from the [Labour force survey \(LFS\)](#) , analysed by working time (full/part-time), working status, age, level of education, sex, permanency and seniority of work with the same employer (annual and quarterly data);
- data on personal travel receipts and expenditure from the [balance of payments](#) ;
- [transport statistics](#) (for example, air passenger transport);
- [structural business statistics \(SBS\)](#) may be used to provide additional information on tourism flows and on the economic performance of certain tourism-related sectors.

Context

The EU is a major tourist destination, with six Member States among the world's top ten destinations for holidaymakers. Tourism has the potential to contribute towards employment and economic growth, as well as to development in rural, peripheral or less-developed areas. These characteristics drive the demand for reliable and harmonised statistics within this field, as well as within the wider context of regional policy and sustainable development policy areas.

Tourism can play a significant role in the development of European regions. Infrastructure created for tourism purposes contributes to local development, while jobs that are created or maintained can help counteract industrial or rural decline. Sustainable tourism involves the preservation and enhancement of cultural and natural heritage, ranging from the arts to local gastronomy or the preservation of [biodiversity](#) .

In 2006, the [European Commission](#) adopted a Communication titled '[A renewed EU tourism policy: towards a stronger partnership for European tourism](#) ' (COM(2006) 134 final). It addressed a range of challenges that will shape tourism in the coming years, including Europe's ageing population, growing external competition, consumer demand for more specialised tourism, and the need to develop more sustainable and environmentally friendly tourism practices. It argued that more competitive tourism supply and sustainable destinations would help raise tourist satisfaction and secure Europe's position as the world's leading tourist destination. It was followed in October 2007 by another Communication, titled '[Agenda for a sustainable and competitive European tourism](#) ' (COM(2007) 621 final), which proposed actions in relation to the sustainable management of destinations, the integration of sustainability concerns by businesses, and the awareness of sustainability issues among tourists.

The [Lisbon Treaty](#) acknowledged the importance of tourism – outlining a specific competence for the EU in this field and allowing for decisions to be taken by a qualified majority. An article within the Treaty specifies that the EU 'shall complement the action of the Member States in the tourism sector, in particular by promoting the competitiveness of Union undertakings in that sector'. '[Europe, the world's No. 1 tourist destination – a new political framework for tourism in Europe](#) ' (COM(2010) 352 final) was adopted by the European Commission in June 2010. This Communication seeks to encourage a coordinated approach for initiatives linked to tourism and defined a new framework for actions to increase the competitiveness of tourism and its capacity for sustainable growth. It proposed a number of European or multinational initiatives – including a consolidation of the socio-economic knowledge base for tourism – aimed at achieving these objectives.

Foreign direct investment statistics

Data from June 2012. Most recent data: Further Eurostat information, Main tables and Database .

This article gives an overview of foreign direct investment (FDI) statistics for the European Union (EU) in relation to year-end stocks, annual flows and income. The analysis mainly covers the period 2008 to 2010, but provisional data on FDI flows for 2011 are also included; note that the latter are based on provisional quarterly figures that have been annualised for the purpose of this analysis.

FDI flows experience recovery in 2011 after a downturn in 2008-2010

In 2011, EU-27 FDI flows showed signs of recovery following the recent financial and economic crisis. Outward flows of FDI increased for the first time in four years, rising by 154% when compared with 2010. At the same time, inward flows of FDI also more than doubled compared with the previous year — up 117%. Nevertheless, despite the large increases in EU-27 FDI flows in 2011, these gains only partially compensated the considerable declines that were recorded during the crisis (2008 to 2010). As a result, EU-27 FDI flows with the rest of the world still remained, in 2011, well below their record peaks of 2007 for both inward and outward flows.

In 2011, EU-27 investment vis-à-vis the rest of the world (extra-EU-27 flows) increased, which may reflect the start of a global economic recovery. FDI flows channelled through special purpose entities (SPE)¹⁶⁵ played a significant role (as in previous years) when analysing the results for 2011.

In 2009, EU-27 FDI outflows dropped by 17%, mainly due to a decrease of 'other capital'. This pattern continued and strengthened in 2010, as outflows fell by a further 54%, as a result of a sharp drop in equity capital invested outside the EU-27.

Following a slight recovery in 2009, EU-27 inward flows declined sharply in 2010, falling by 56% compared with the year before, mirroring the losses that were recorded for outflows (see Figure 1). Equity and other capital both contributed to the negative development in 2010, while reinvested earnings continued to follow a positive trend (a pattern that has been observed since 2008).

¹⁶⁵Special Purpose Entities are mainly financial holding companies, foreign-owned, and principally engaged in cross-border financial transactions, with little or no activity in the Member State of residence.

The rate of return on FDI stocks for both EU-27 outward and inward investment rose in 2010 when compared with the previous year, but remained well below the record levels of 2007 (see Figure 3).

During the period 2008 to 2010, EU-27 FDI flows were largely affected by the global financial and economic crisis. In 2010, both outward and inward flows of FDI halved when compared with the previous year. As in 2009, the decline in EU-27 investment abroad was mainly due to a sharp drop in transactions with the EU-27's main partners — the United States (down 75% to EUR 20.9 billion) and Switzerland (down to EUR 0.9 billion — for the purpose of this article a billion is defined as a thousand million). In 2010, outward flows of FDI to offshore financial centres (OFC) also fell sharply to EUR 5.3 billion, in part due to disinvestment in central America, where some OFCs are located.

The same three partners (the United States, Switzerland and OFCs) also played a prominent role when analysing the development of inward FDI flows into the EU-27 in 2010. Flows from the United States and Switzerland declined by 51% and 67% respectively, while OFCs recorded a disinvestment of EUR 7.8 billion. SPEs played an important role in all of these developments.

On the other hand, there was some evidence of new partners gaining in importance for EU-27 investment. For example, EU-27 FDI outflows to Brazil tripled from 2008 to 2011 and in 2010, Brazil became the main destination for EU-27 outflows of FDI, ahead of the United States (see Table 1).

Provisional figures for 2011 show signs of a recovery in EU-27 outflows to all of the EU's main partners, aside from Russia, where the EU-27 recorded a disinvestment of EUR 2.3 billion. EU-27 FDI with the United States, Switzerland and OFCs grew substantially, to account for 54% of total outflows to the rest of the world in 2011 and for 73% of total inflows.

Outward FDI to Canada dropped into disinvestment in 2010, but recovered in 2011 when investment of EUR 12.4 billion was recorded. In 2010, Canada was the second largest investor in the EU-27 (EUR 23.9 billion), but this figure was down to EUR 6.8 billion in 2011.

EU-27 investment flows with economies in south east Asia were less affected by the financial and economic crisis. There were indications of a recovery in investment levels in 2010, except for Japan, where the EU-27 recorded disinvestment in both directions (inward and outward FDI). Preliminary results for 2011 show that levels of EU-27 FDI rose further, with China (EUR 17.5 billion) and India (EUR 12.0 billion) being the main destinations for outward FDI, and Hong Kong (EUR 6.5 billion) and Japan (EUR 5.4 billion) being the main sources of inward FDI.

In 2010, Australia attracted 10% (EUR 14.9 billion) of the EU-27's total investment abroad, but withdrew (disinvestment) some EUR 1.9 billion of FDI from the EU-27, reversing the pattern of bilateral FDI relations that had been recorded in 2009.

EU-27 outward FDI

FDI flows can vary considerably from one year to another, as they are often influenced by large mergers and acquisitions. Luxembourg reported a large share (36%) of EU-27 FDI outward flows (when averaged over a three-year period from 2009 to 2011), largely as a result of the importance of special purpose entities (some 85% of Luxembourg's total direct investment). SPEs also played an important role in some other EU Member States, especially the Netherlands and Hungary; note that the data for these two countries exclude SPEs.

Luxembourg's outgoing FDI halved in 2010 compared with 2009, though Luxembourg remained the leading EU investor in non-member countries. Bermuda, the United States and Switzerland were the three top destinations for FDI from Luxembourg, showing the importance of the financial sector for this country.

The United Kingdom recorded a sharp drop in its investment in non-member countries. In 2010, there was even disinvestment for a number of its traditional partners like the United States and Canada, though its investment levels increased in south east Asia, Australia and Brazil.

EU-27 FDI stocks with moderate growth in 2010

EU-27 outward and inward FDI stocks (or positions) grew steadily in 2010: outward stocks rose by 13% and inward stocks by 12%, compared with gains of 10% and 6% respectively in 2009.

North America continues to hold the biggest share of outward stocks of FDI among non-member countries

At the end of 2010, North America had the biggest share (34%) of outward FDI stocks from the EU-27. The United States accounted for some 28% (EUR 1195.0 billion) of the total, although there was some evidence of a slowdown in the pace of growth of outward FDI stocks from the EU-27 (up 5.7% during the year to the end of 2010). The main holders of outward stocks of FDI in the United States were the United Kingdom (18% of the EU-27 total), France (14%) and Germany (14%).

Switzerland was the second most important destination for outward stocks of EU-27 FDI in 2010, accounting for 14% of the total; the main area of activity was the financial and insurance activities sector. Canada was the third largest destination for outward stocks of EU-27 FDI, with a 4.8% share of the total.

EU-27 stocks of FDI in Brazil grew by 73% during the period from 2008 to 2010, underlining the growing activity of EU-27 investors in this country.

In Asia, the most important destinations for outward stocks of EU-27 FDI were Singapore, Hong Kong and Japan, together accounting for half of the EU-27's positions in Asia in 2010. The relative importance of China as a destination for EU-27 FDI has grown steadily over recent years, and outward FDI stocks reached EUR 75.1 billion by the end of 2010, which was higher than in South Korea, India and Indonesia (the next largest partners).

In Africa, the main destinations for outward stocks of EU-27 FDI were South Africa (EUR 92.2 billion), Nigeria (EUR 34.5 billion) and Egypt (EUR 24.4 billion). EU-27 stocks in South Africa grew by 19% to the end of 2010, and South Africa remained among the top ten partners for outward stocks of EU-27 FDI (see Table 2).

The United States was the main holder of inward FDI stocks in the EU-27

At the end of 2010, the United States accounted for 41% (EUR 1201.4 billion) of the EU-27's inward stocks of FDI from the rest of the world. The United States thus consolidated its position as the major holder of FDI stocks in the EU-27, having invested mostly in financial and insurance activities and manufacturing (one third of the latter being in metal and machinery manufacturing).

Switzerland was the second largest holder of inward FDI stocks in the EU-27 with EUR 365.4 billion in 2010 — this was 10% more than in 2009.

Other countries with significant shares of inward FDI stocks in the EU-27 included Canada, Japan, Brazil, Singapore, Hong Kong and Russia. Canada and Japan held 14% and 4% more FDI stocks respectively in 2010 compared with the previous year. In 2010, the highest annual growth among these partners was achieved by Hong Kong (51%), followed by Singapore (34%) and Brazil (21%).

Continued activity dominance for the services sector

The sectoral structure of EU-27 FDI stocks (analysed according to the [NACE Rev. 2](#) classification) remained more or less unchanged in 2009. The EU-27 had a positive FDI balance vis-à-vis the rest of the world for all major sectors.

Services made by far the largest contribution to both outward (57%) and inward (63%) stocks of extra-EU-27 FDI by the end of 2009, and this sector's respective shares were slightly greater than at the end of 2008; this is in keeping with the relative weight of services within the whole economy and also its gradually increasing share of total economic activity. Almost two thirds of EU-27 outward and inward stocks of services FDI were held in financial and insurance activities at the end of 2009, and the relative weight of this economic activity grew

substantially when compared with 2008. Almost all services subsectors contributed to the positive development, except for distributive trades (including repair of motor vehicles) and information and communication, where both outward and inward stocks of EU-27 FDI decreased.

EU-27 FDI stocks in manufacturing declined in 2009 both outward (-4%) and inward (-5%), reducing the importance of these activities to around 20% of total stocks. FDI stocks in construction shrank by almost a quarter during the year to the end of 2009, to record the largest annual fall among the main economic activities shown in Table 3.

EU net income recovers in 2010

Following successive declines in 2008 and 2009, the EU-27's net income from FDI recovered somewhat in 2010, as rates of return¹⁶⁶ on FDI stocks rose to 6.9% for outward FDI and 5.2% for inward FDI.

EU-27 investment income grew by 36%, almost fully cancelling out the reductions that were recorded during the previous two years. The income paid to non-member countries increased to EUR 139.5 billion, exceeding the record level of 2007. The resulting net income from the rest of the world amounted to EUR 111.6 billion — which was 43% more than in 2009. The EU-27's income balance for FDI in 2010 was equal to 0.91% of GDP, compared with 0.61% in 2009.

Data sources and availability

Foreign direct investment statistics in the EU are collected in accordance with Regulation (EC) No 184/2005 of the European Parliament and of the Council on Community statistics concerning balance of payments, international trade in services and foreign direct investment.

The methodological framework used is that of the [OECD benchmark definition of foreign direct investment - third edition](#), which provides a detailed operational definition that is fully consistent with the [IMF's](#) balance of payments manual (fifth edition).

This article is based on FDI data that were available in Eurostat's database at the beginning of June 2012. The series in the database cover the period from 1992-2010, analysed by partner, activity and type of investment (equity capital, loans and reinvested earnings). More aggregated FDI figures that are presented in this article for 2011 are provisional results based on annualised quarterly balance of payments data.

EU-27 aggregates include special purpose entities (SPEs), which are a particular class of enterprises (often empty shells or holding companies) not included in all countries' national statistics. Consequently, EU-27 aggregates are not simply the sum of national figures.

Context

In a world of increasing globalisation, where political, economic and technological barriers are rapidly disappearing, the ability of a country to participate in global activity is an important indicator of its performance and competitiveness. In order to remain competitive, modern-day business relationships extend well beyond the traditional foreign exchange of goods and services, as witnessed by the increasing reliance of enterprises on mergers, partnerships, joint ventures, licensing agreements, and other forms of business cooperation.

FDI may be seen as an alternative economic strategy, adopted by those enterprises that invest to establish a new plant/office, or alternatively, purchase existing assets of a foreign enterprise. These enterprises seek to complement or substitute external trade, by producing (and often selling) goods and services in countries other than where the enterprise was first established.

There are two kinds of FDI: namely, the creation of productive assets by foreigners, or the purchase of existing assets by foreigners (for example, through acquisitions, mergers, takeovers). FDI differs from portfolio

¹⁶⁶The FDI rate of return is measured here as (FDI income of year t) / (stock of FDI at the end of year t-1).

investments because it is made with the purpose of having control, or an effective voice, in the management of the enterprise concerned and a lasting interest in the enterprise. Direct investment not only includes the initial acquisition of equity capital, but also subsequent capital transactions between the foreign investor and domestic and affiliated enterprises.

Conventional trade is less important for services than for goods. While trade in services has been growing, the share of services in total [intra-EU](#) trade has changed little during the last decade. However, FDI is expanding more rapidly for services than for goods, and is increasing at a more rapid pace than conventional trade in services. As a result, the share of services in total FDI flows and positions has increased substantially, as the service sector has become increasingly international.

Figure 2: Extra-EU trade in services, by main categories, EU-27, 2011 (1)(EUR1000 million) - Source: Eurostat (bop_its_det)

This article provides information in relation to international trade in services for the [European Union \(EU\)](#) , the EU Member States, some [EFTA](#) and [candidate countries](#) , as well as Japan and the United States. Its main focus is to provide information on the EU's main trading partners for services, while it also presents an analysis of international trade by type of service.

Services play a major role in all modern economies. An efficient services sector is considered to be crucial for trade and economic growth and for vibrant and resilient economies. Services provide vital support to the economy and industry as a whole, for example, through finance, logistics and communications. Increased trade in services and the widespread availability of services may boost economic growth by improving the performance of other industries, since services can provide key intermediate inputs, especially in an increasingly interlinked, globalised world.

Main statistical findings

The share of services in EU-27 exports (extra-EU) of goods and services was relatively stable during the period from 2001 to 2008, fluctuating between 28% and 29%. This share rose to 30.3% in 2009, before falling back to 28.6% in 2010 and falling still further to 27.4% in 2011 (its lowest share in more than a decade). The services share of EU-27 imports (extra-EU) of goods and services peaked at 26.49% in 2002, after which there were four consecutive contractions. From a relative low of 22.3% in 2006, the share of services in EU-27 imports of goods and services remained relatively unchanged until 2009 when there was a sharp increase to 25.9%. The relative importance of services fell once again after this date, accounting for 21.8% of EU-27 imports of goods and services in 2011 (also the lowest proportion for more than a decade).

The EU-27 reported a surplus in service transactions of EUR 109100 million with the rest of the world in 2011 (provisional), reflecting credits of EUR 579500 million and debits of EUR 470400 million (see Table 1).

The United Kingdom recorded a surplus (extra and intra-EU combined) of EUR 76600 million in service

transactions in 2011, the largest value among the Member States and considerably more than the next highest levels that were recorded by Spain (EUR 34000 million) and Luxembourg (EUR 23000 million). In contrast, Germany recorded a deficit in service transactions of EUR 21600 million in 2011, the largest deficit by far among the Member States. It is important to underline that the majority of the international trade in services made by Member States involved intra-EU transactions, amounting to 55.7% of credits and 58.5% of debits in 2011.

Northern America was the main extra-EU trading region for the EU-27's international trade in services in 2010, accounting for 26.4% of total credits and 31.4% of total debits (see Figure 1). The EU-27's largest net balances for services were recorded with Asian, EFTA and Arabian Gulf countries (surpluses in excess of EUR 11000 million in 2010). The EU-27 also posted a surplus with most other regions, although negative balances for services were recorded with central America (EUR 5200 million), northern Africa (EUR 5000 million) and northern America (EUR 110 million).

Table 6 provides similar information on the development of trade in services for a set of selected trading partners for a range of countries rather than regions. It shows that the main trading partner for the EU-27 in 2011 (provisional data) was the United States, with credits and debits almost balanced. The largest surplus for trade in services was recorded with Russia (EUR 11800 million).

More than two thirds of the EU-27's credits (67.7%) and debits (70.0%) in the international trade of services in 2011 were accounted for by three categories: transport, travel and other business services (see Figure 2). The surplus of EUR 45900 million for other business services was the highest among services, followed by surpluses of EUR 26300 million for computer and information services, EUR 25900 million for financial services and EUR 21800 million for transport. In contrast, the largest deficits were EUR 8500 million for royalties and license fees and EUR 4600 million for travel.

Data sources and availability

The main methodological references used for the production of statistics on international trade in services are the [International Monetary Fund \(IMF\)](#) 's fifth [balance of payments](#) manual (BPM5) and the [United Nations](#) ' [manual on statistics of international trade in services](#) . The sixth edition of the balance of payments manual (BPM6) was finalised in December 2008 with implementation planned for 2014.

The transmission of data on international trade in services to [Eurostat](#) is covered by [Regulation \(EC\) No 184/2005 of the European Parliament and of the Council](#) .

International trade in services is geographically allocated according to the residence of the trading partner, distinguishing between: intra-EU transactions which correspond to the sum of transactions declared by EU Member States with other EU Member States; extra-EU transactions which correspond to the transactions declared by EU Member States with countries outside the EU. World transactions are equal to the sum of intra-EU transactions and extra-EU transactions.

The breakdown of Eurostat statistics on international trade in services includes three main sub-items: transport, travel, and other services.

- Transport covers all transport services that are provided by residents of one economy for those of another and that involve the carriage of passengers, the movement of goods (freight), rentals (charters) of carriers with crew, and related supporting and auxiliary services. All modes of transport are considered including sea, air, space, rail, road, inland waterway, and pipelines, as are other supporting and auxiliary services (such as storage and warehousing).
- Travel covers primarily the goods and services acquired from an economy by travellers during visits of less than one year to that economy. The goods and services are purchased by, or on behalf of, the traveller or provided, without a quid pro quo (that is, are provided as a gift), for the traveller to use or give away. The transportation of travellers within the economies that they are visiting, where such transportation is provided by carriers not resident in the particular economy being visited, as well as the international carriage of travellers are excluded; both are covered in passenger services under transport. Also excluded are goods purchased by a traveller for resale in the traveller's own economy or in any other economy. Travel is divided in two subcomponents: business travel and personal travel.

- Other services comprise external transactions not covered under transport or travel, specifically: communications services, construction services, insurance services, financial services, computer and information services, royalties and licence fees, other business services, personal, cultural and recreational services, and government services.

Context

The provision of services contributes an increasing share of the economic wealth of the EU, and accounts for more than 50% of GDP in each Member State. Nevertheless, the value of exports and imports of goods is generally two to three times higher than that of services. Part of this imbalance may be due to the nature of some services: for example, professional services that are bound by distinct national legislation. Another difference between goods and services concerns the immediacy of the relationship between supplier and consumer. Many services are non-transportable, in other words, they require the physical proximity of the service provider and consumer. This proximity requirement implies that many services transactions involve factor mobility. Thus, an important feature of services is that they are provided via various modes of supply. Often services are tailored according to the client's needs and tastes and hence tend not to be homogeneous or mass-produced. For international trade in non-transportable services to take place, either the consumer must go to the service provider or the service provider must go to the consumer. As such, services cover a heterogeneous range of products and activities that are difficult to encapsulate within a simple definition. Services are also often difficult to separate from goods with which they may be associated or bundled.

Despite the relatively low level of international trade in services, there are a number of reasons to believe that this level may grow in future years. Technological developments have increased the tradability of some services, for example facilitating web-based services such as those for finance, education, health and government amongst others. Furthermore, liberalisation efforts are likely to facilitate and therefore stimulate international trade in services. Globally, the inclusion of services in the [Uruguay Round](#) of trade negotiations led to the general agreement on trade in services ([GATS](#)) that entered into force in January 1995. The GATS aims at ensuring increased transparency and predictability of relevant rules and regulations, and promoting progressive liberalisation through successive rounds of negotiation.

Within the EU the objective of the [Services Directive 2006/123/EC](#) of 12 December 2006, on services in the internal market, is to eliminate obstacles to trade in services, thus allowing the development of cross-border operations, making it easier for service businesses to set up or sell their services elsewhere in the EU. The Directive requires Member States to set up 'Points of Single Contact' to assist business through the provision of information relating to offering services abroad. The Directive is intended to improve [competitiveness](#) , not just of service enterprises but also of EU business as a whole, while providing greater choice and improved quality for consumers.

At the end of May 2012 the European Commission confirmed that all Member States had officially transposed the Services Directive into national law. Following Article 41 of the Directive (which calls for a comprehensive report on the application of the Directive), the European Commission released on 8 June 2012 a Communication titled ' [A partnership for new growth in services 2012-2015](#) ' (COM(2012) 261 final). The Communication formed part of a wider 'services package': a set of proposals designed to stimulate growth and release the full potential of the services market.

International trade in goods

Extra-EU trade in goods

Data from July 2012. Most recent data: Further Eurostat information, Main tables and Database .

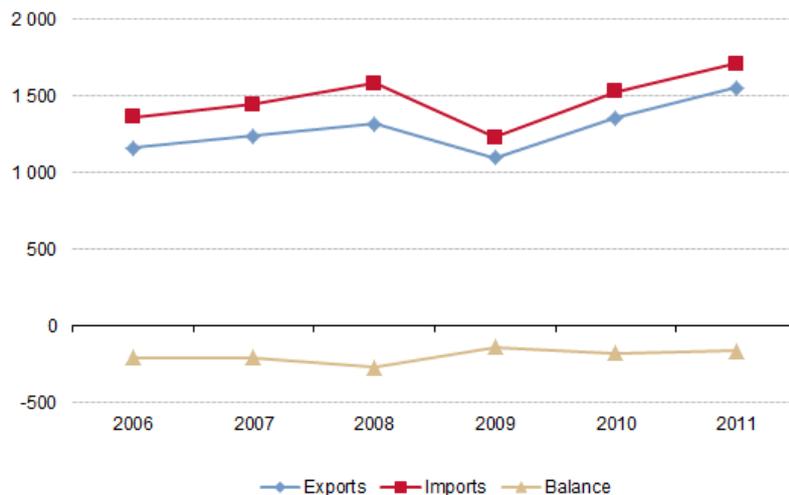

Figure 1: Evolution of extra EU-27 trade, 2006-2011(EUR 1 000 million) - Source: Eurostat (TET00018)

International trade - especially the size and evolution of imports and exports - is an important indicator of the performance of the European Union (EU) economy, showing how it interacts with other countries and its status in the international economy.

This article takes a close look at recent trends in imports and exports, focusing on extra-EU trade, the main trading partners, and the most traded products.

Main statistical findings

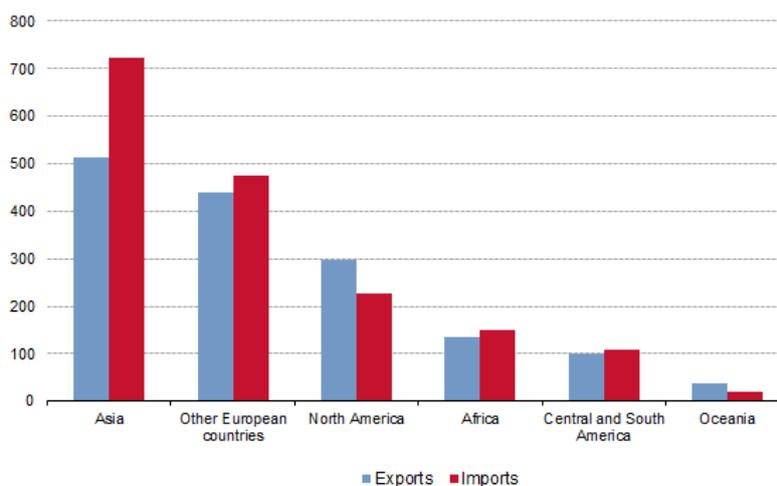

Figure 2: EU trade by geographical zone, 2011(EUR 1 000 million) - Source: Eurostat (ext_lt_maineu)

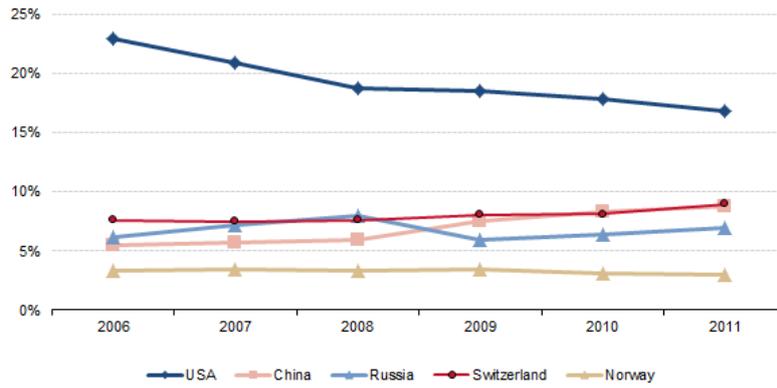

Figure 3: Main trading partners' shares of EU exports, 2006-2011 (EUR 1 000 million) - Source: Eurostat (TET00040)

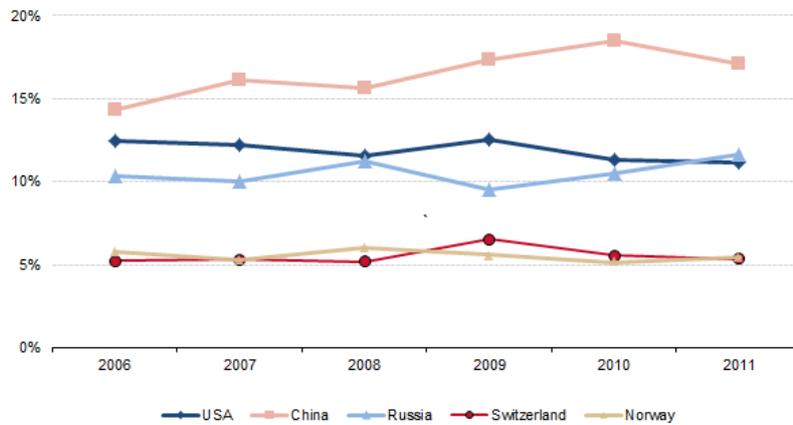

Figure 4: Main trading partners' shares of EU imports, 2006-2011 (EUR 1 000 million) - Source: Eurostat (TET00040)

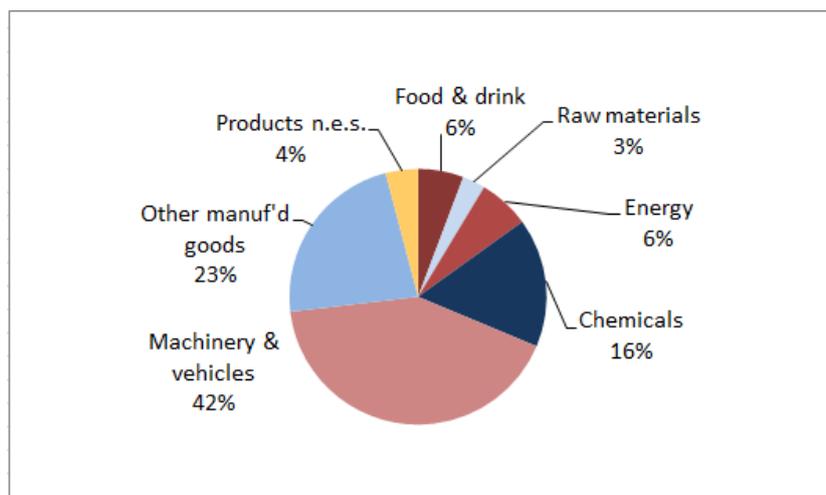

Figure 5: EU exports by products group, 2011 (%) - Source: Eurostat (TET00061)

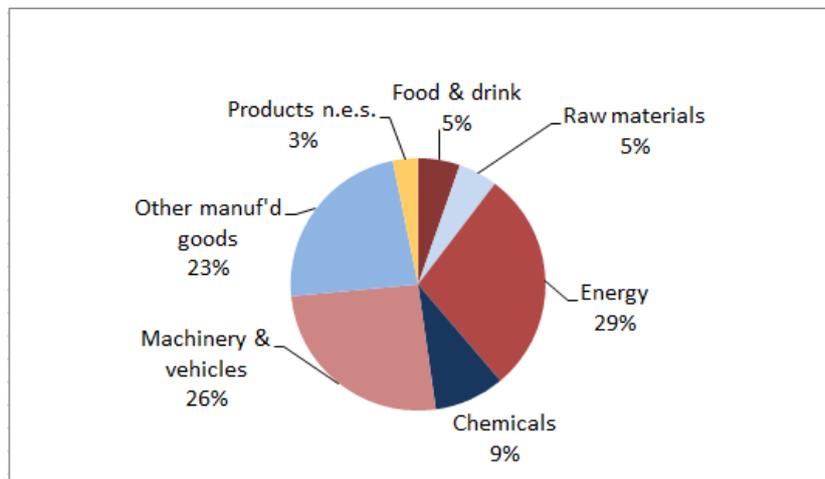

Figure 6: EU imports by products group, 2011(%) - Source: Eurostat (TET00061)

The rapid decline in both imports and exports recorded by the European Union in 2009, following the financial turmoil at the end of 2008, was completely reversed in 2011. Both EU exports and imports reached a record level, summing up to more than EUR 3000 billion. EU trade is characterised by a permanent but generally limited trade deficit. In 2011 the deficit was valued at EUR 160 billion, which was a little less than the deficit registered in the previous year.

In 2011 over 40% of EU imports came from Asian countries while the other European countries accounted for more than a quarter. The main destination for EU exports in 2009 was Asia with about one third of the total, followed by other European countries (28%) and North America (19%). The EU has a considerable deficit in trade with Asian countries, while the largest surplus is recorded in trade with North America.

Main EU partners

The USA has traditionally been the EU's major trading partner but its relative significance has declined in recent years, in particular in exports. Between 2006 and 2011 the US proportion of total EU exports fell from 23% to 17%. Nevertheless, from 2009 the surplus with the USA has been increasing, and in 2011 it reached a record level since 2008. China has become a main player in world trade in recent years. The EU trade with China has more than quadrupled since 2000. China currently ranks first among EU imports suppliers, after overtaking the USA in 2006, and is the third destination for EU exports, just after Switzerland. Since 2000 the EU has recorded the largest bilateral deficit in trade with China. Other large deficits were measured in trade with Russia, Norway and Japan. The EU posts the only large-scale trade surplus in trade with the USA.

EU trade by main product groups

The EU exports mainly manufactured products: their share has annually been over 80% of total EU exports. In 2011 machinery and vehicles made up 42% of the total exports while other manufactured goods accounted for 23% and chemical products for 16%. Primary products account for 15% of total exports; the most exported products within this category are energy products (with a share of 43%) and food and drink (38%).

The structure of imports has slightly changed in recent years. Between 2006 and 2011, the share of primary products increased from 35% to 39% while the respective share of manufactured goods declined. The main reason behind this is the rapid growth of imports of energy products. The majority of the imports (about 60%) are manufactured goods. The breakdown diverges from exports: machinery and vehicles and chemical products account for a smaller share while the share of other manufactured goods is similar to that for exports. The surplus in trade of manufactured goods more than doubled from 2006 to 2011. The deficit in trade of primary products showed a rapid increase during the last two years, mainly driven by the growing deficit in energy products.

Data sources and availability

EU data comes from [Eurostat](#) 's [COMEXT](#) database.

COMEXT is the Eurostat reference database for international trade. It provides access not only to both recent and historical data from the EU [Member States](#) but also to statistics of a significant number of third countries. International trade aggregated and detailed statistics disseminated from Eurostat website are compiled from COMEXT data according to a monthly process. Because COMEXT is updated on a daily basis, data published on the website may differ from data stored in COMEXT in case of recent revisions.

EU data are compiled according to community guidelines and may, therefore, differ from national data published by Member States. Statistics on extra-EU trade are calculated as the sum of trade of each of the 27 Member States with countries outside the EU. In other words, the EU is considered as a single trading entity and trade flows are measured into and out of the area, but not within it.

Context

Europe is the world's largest exporter of manufactured goods and services, and is itself the biggest export market for more than one hundred countries. Trade is an important indicator of Europe's prosperity and place in the world, and the bloc has become deeply integrated into global markets both for the products it sources and the exports it sells.

Because the 27 Member States of the European Union share a single market and a single external border, they also have a single trade policy. Both in the [World Trade Organization](#) , where the rules of international trade are agreed and enforced, and with individual trading partners, EU Member States speak and negotiate collectively.

Extra-EU trade in manufactured goods

Data from July 2012. Most recent data: Further Eurostat information, Main tables and Database .

This article focuses on the structure and evolution of the [European Union \(EU\)](#) international trade in [manufactured goods](#) : [imports](#) and [exports](#) at EU level.

The [Standard international trade classification \(SITC\)](#) distinguishes four main categories (sections) of manufactured goods:

- chemicals (SITC 5);
- manufactured goods classified chiefly by material (SITC 6);
- machinery and vehicles (SITC 7);
- miscellaneous manufactured articles (SITC 8);

Sections 6 and 8 are often grouped together as 'other manufactured goods'.

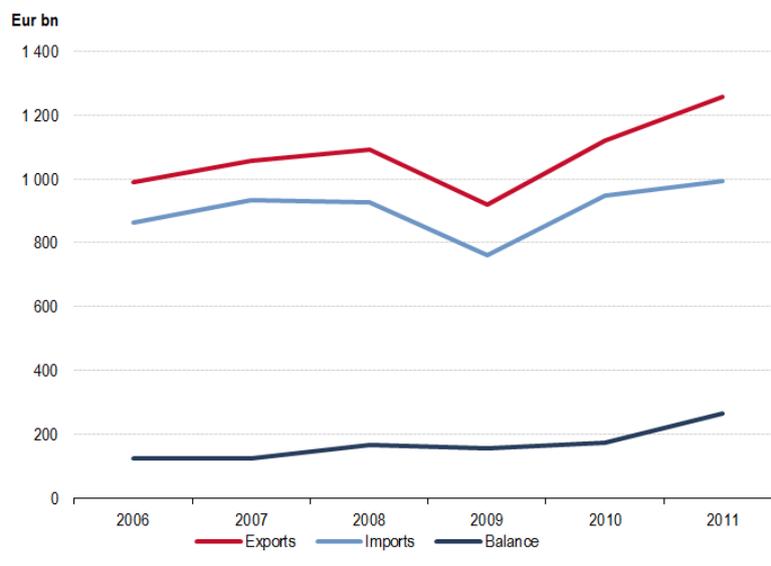

Figure 1: EU trade in manufactured goods, 2006-2011 (EUR 1 000 million)Source: Eurostat (TET00061)

Main statistical findings

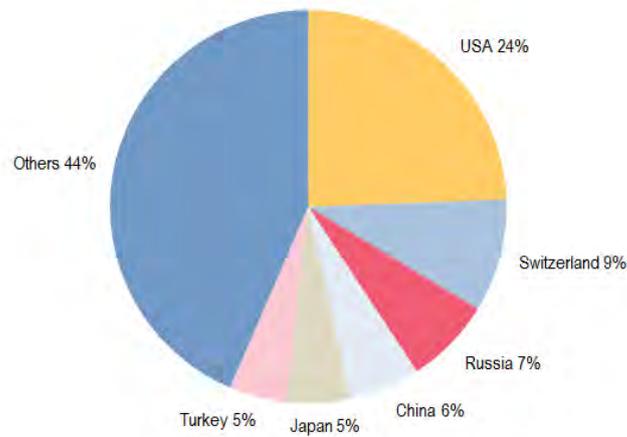

Figure 2: Main trading partners' shares of EU exports of chemical products, 2011 (%) Source: Eurostat (TET00044)

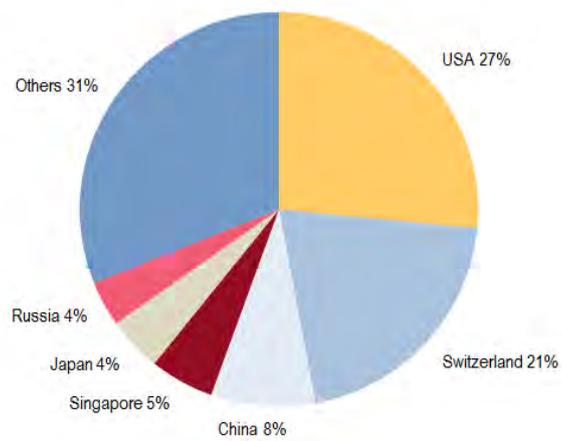

Figure 3: Main trading partners' shares of EU imports of chemical products, 2011 (%) Source: Eurostat (TET00044)

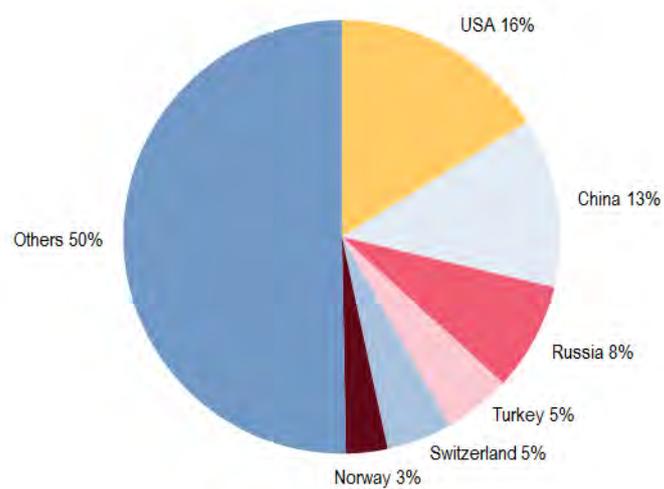

Figure 4: Main trading partners' shares of EU exports of machinery and vehicles, 2011 (%) Source: Eurostat (TET00045)

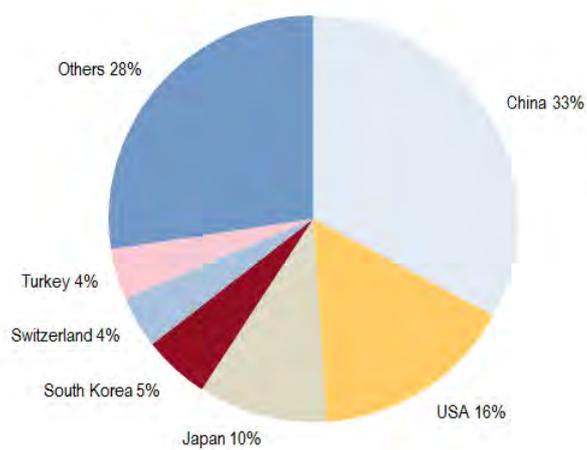

Figure 5: Main trading partners' shares of EU imports of machinery and vehicles, 2011 (%) Source: Eurostat (TET00045)

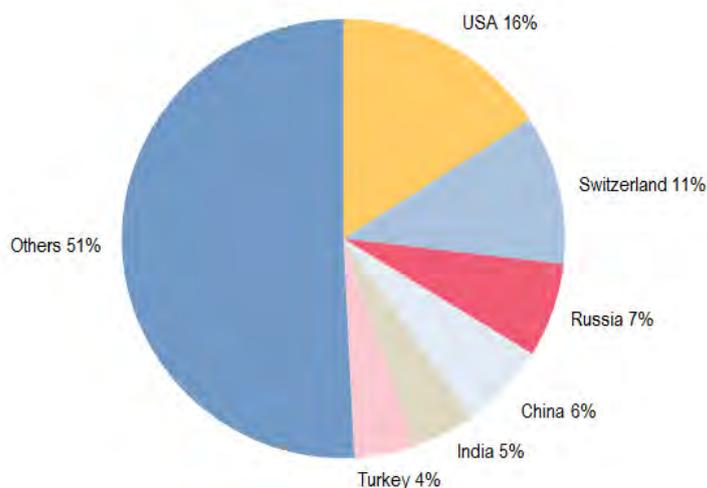

Figure 6: Main trading partners' shares of EU exports of other manufactured goods, 2011 (%) Source: Eurostat (TET00046)

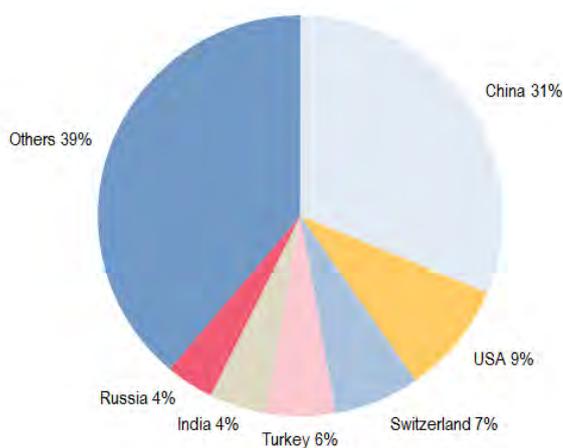

Figure 7: Main trading partners' shares of EU imports of other manufactured goods, 2011 (%) Source: Eurostat (TET00046)

The EU **exports** consist mainly of manufactured products: their share has annually been more than 80% of total EU exports. In 2011, exports of 'machinery and vehicles' and 'other manufactured goods' together reached EUR 1000 billion, with an increase of about 40% in comparison with the lower level of 2009.

About 60% of EU **imports** are manufactured goods. The breakdown diverges from exports: 'machinery and vehicles' and chemical products account for a smaller share while the share of 'other manufactured goods' is similar to that for exports.

The **surplus** in trade of manufactured goods reached a peak of EUR 264 billion in 2011, more than double of the surplus registered in 2006.

Chemicals

The chemicals sector (SITC Section 5) contains various chemical goods such as organic chemicals, inorganic chemicals, plastics and pharmaceutical products.

Trade in chemicals has grown steadily from 2006 to 2011 but its share of the total EU trade has remained quite stable: in 2011 chemicals accounted for 16% of exports and 9% of imports. Besides machinery and vehicles, the chemicals sector is the only product group where the EU posts a trade surplus. The surplus reached almost EUR 100 billion in 2011.

The most important products within the group, both for exports and imports, are pharmaceutical products and organic chemicals.

Majority of imports come from a small number of countries: in 2011 the six biggest suppliers accounted for over two thirds of total EU imports. The USA was the main source, with a proportion of 27%, followed by Switzerland with 21%. The USA (24% in 2011) and Switzerland (9%) were also the main partner countries for exports.

Machinery and vehicles

'Machinery and vehicles' (SITC Section 7) includes power generating and industrial machinery, computers, electric and electronic parts and equipment, road vehicles and parts, ships, airplanes and railway equipment.

'Machinery and vehicles' is the most important individual product group in the external trade of the EU, accounting for 42% of the total EU exports and 26% of imports in 2011. The group records also the largest surplus in EU trade: EUR 208.7 billion in 2011.

The main exported products within the group are road vehicles, industrial machinery and electrical machinery, while the imports are dominated by electrical machinery, telecommunications equipment and IT products.

The USA is the biggest destination country of EU exports, although its proportion diminished from 22% to 16% between 2006 and 2011. Concerning the other main partner countries, exports to China and Russia increased strongly during the same period.

The USA and Japan are still two of the top three source countries for imports although their importance has decreased. In 2006 they covered 33% of EU imports but only 26% in 2011. During the same period China's share increased from 23% to 33%.

Other manufactured goods

'Other manufactured goods' (SITC Sections 6 and 8) is a heterogeneous group consisting of manufactured goods which range from basic semi-manufactured goods such as leather, rubber, wood, paper, textiles, metals, building fixtures and fittings to more labor-intensive products like clothes, shoes and accessories, scientific instruments, clocks, watches and cameras.

The structure of exports and imports, in terms of products, differs to some extent. The EU exports more semi-manufactured goods such as metals and metal products while for imports manufactured goods are more relevant, in particular clothing.

After a fall in 2009, the value of both imports and exports rose constantly in 2010 and 2011. In this products group the EU posts a trade deficit that reached its maximum in 2007 (EUR -72.5 billion), but then remained quite far from that record.

Since overtaking the USA in 2001, China has been the biggest supplier to the EU in this product group, representing a share of 31% in 2011. Other important suppliers include the USA, Switzerland and Turkey. The main destinations for exports are the USA, Switzerland, Russia and China.

Data sources and availability

EU data come from [Eurostat](#)'s [COMEXT](#) database. COMEXT is the Eurostat reference database for international trade. It provides access not only to both recent and historical data from the EU Member States but also to statistics of a significant number of third countries. International trade aggregated and detailed statistics disseminated from Eurostat website are compiled from COMEXT data according to a monthly process. Because COMEXT is updated on a daily basis, data published on the website may differ from data stored in COMEXT in case of recent revisions.

EU data are compiled according to EU guidelines and may, therefore, differ from national data published by Member States. Statistics on [extra-EU](#) trade are calculated as the sum of trade of each of the 27 Member States with countries outside the EU. In other words, the EU is considered as a single trading entity and trade flows are measured into and out of the area, but not within it.

Context

The EU is the world's biggest exporter of manufactured goods, and is a global market leader for high-quality products. Thanks to some of its key assets such as chemicals, pharmacy products, motor vehicles and non-electrical machinery, the European Union's [trade balance](#) for manufactured products is improving greatly, partially offsetting the rise in the energy deficit.

Extra-EU trade in primary goods

Data from July 2012. Most recent data: Further Eurostat information, Main tables and Database .

This article focuses on the structure and evolution of the [European Union \(EU\)](#) international trade in [primary goods](#) : [imports](#) and [exports](#) at EU level. Primary goods, also called [commodities](#) , are goods sold for production or consumption just as they were found in nature; they include crude oil, coal, iron, and agricultural products like wheat or cotton.

The [Standard international trade classification \(SITC\)](#) distinguishes five main categories (sections) of primary goods:

- food and live animals (SITC 0);
- beverages and tobacco (SITC 1);
- crude materials, excluding fuels (SITC 2);
- mineral fuels (SITC 3);
- animal and vegetable oils, fats and waxes (SITC 4).

Sections 0 and 1 are often grouped together as 'food and drink', 2 and 4 as 'raw materials'.

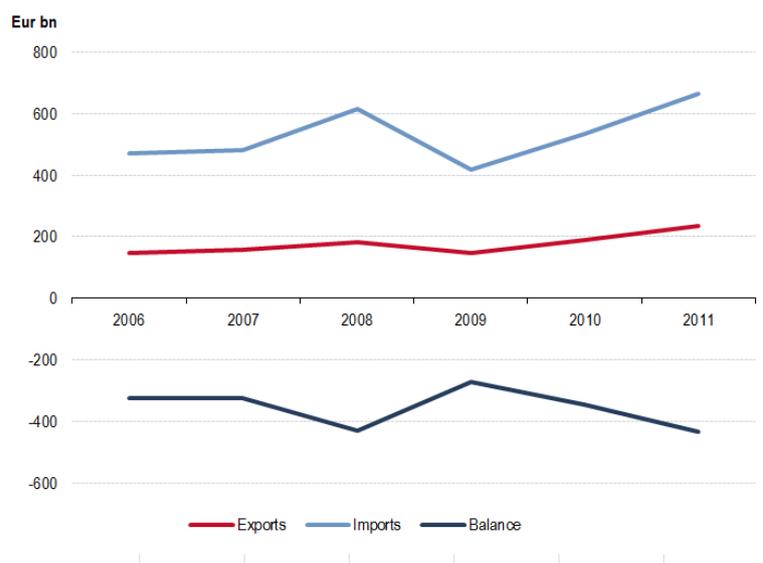

Figure 1: EU trade in primary goods, 2006-2011 (EUR 1 000 million)Source: Eurostat (TET00061)

Main statistical findings

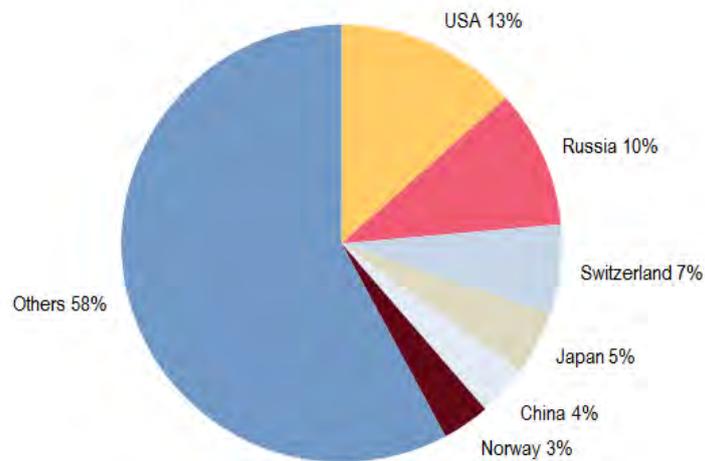

Figure 2: Main trading partners' shares of EU exports of food and drink, 2011 (%) Source: Eurostat (TET00041)

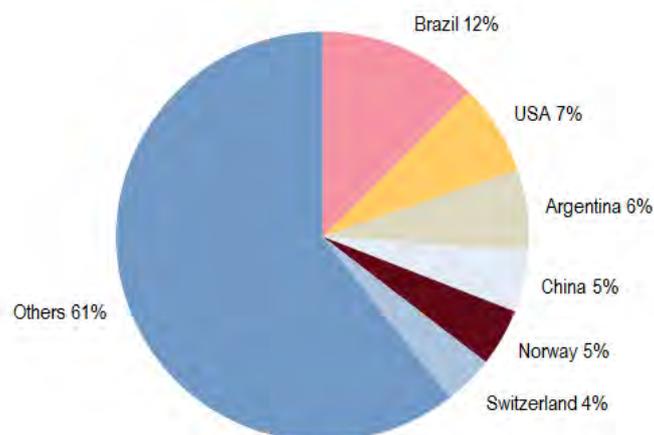

Figure 3: Main trading partners' shares of EU imports of food and drink, 2011 (%) Source: Eurostat (TET00041)

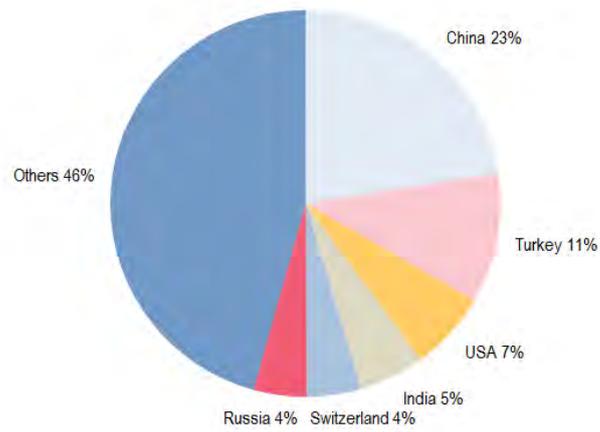

Figure 4: Main trading partners's shares of EU exports of raw materials, 2011 (%)Source: Eurostat (TET00042)

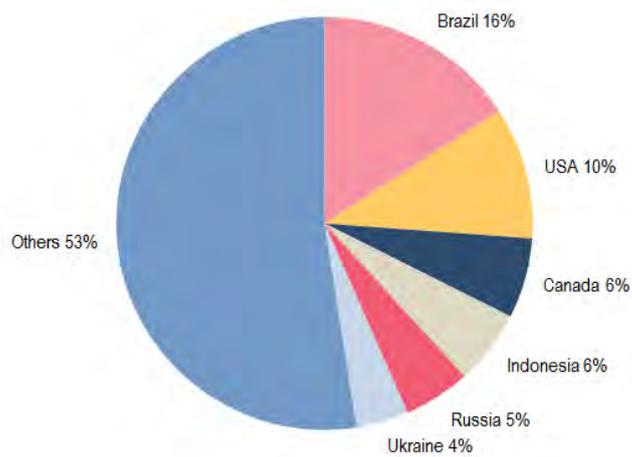

Figure 5: Main trading partners's shares of EU imports of raw materials, 2011 (%)Source: Eurostat (TET00042)

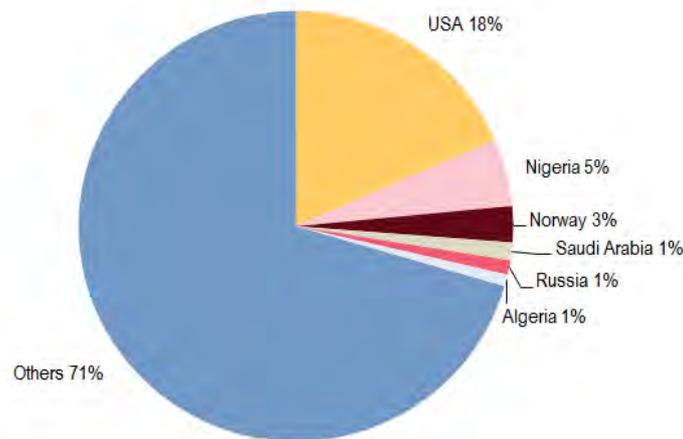

Figure 6: Main trading partners' shares of EU exports of energy products, 2011 (%) Source: Eurostat (TET00043)

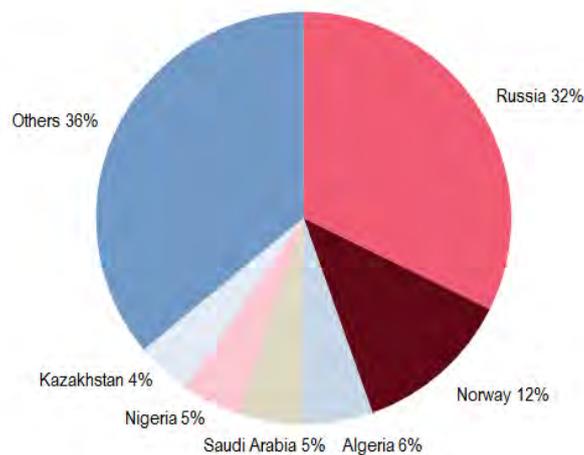

Figure 7: Main trading partners' shares of EU imports of energy products, 2011 (%) Source: Eurostat (TET00043)

In 2011 primary goods accounted for 15% of total EU exports. All groups showed a strong recovering in comparison with 2009, the biggest increase (+76%) was recorded for exports of energy products. In 2011 primary goods represented about two fifth of EU imports, with energy accounting for the biggest share (29%).

Imports of raw materials and energy products increased by over one half between 2008 and 2011. The EU shows a persistent deficit in trade of primary goods, mainly driven by the deficit in energy products, which almost tripled between 2000 and 2011.

Food and drink

Product group 'food and drink' (SITC Sections 0 and 1) includes agricultural products such as food and live animals, beverages and tobacco.

Trade in food and drink remained fairly stable between 1999 and 2004 but rapidly increased from 2005. The EU posted a permanent trade deficit, valued at EUR 2.2 billion in 2011. In exports, beverages are the most

important individual products within the group, accounting for around a quarter of the total. Other main products include [cereals](#) , fruits and vegetables and dairy products.

The USA is the main destination country of the EU exports with a 13% share, followed by Russia, Switzerland and Japan. Coffee and tea, fruit, vegetables and fish make up about 60% of the imports. Brazil, the USA and Argentina are the main suppliers accounting together for about a quarter of total imports.

Raw materials

Raw materials (SITC Sections 2 and 4) include non-manufactured goods like oilseeds, cork, wood, pulp, textile fibres, ores and other minerals as well as animal and vegetable oils.

The EU has an ongoing trade deficit; imports are about the double of the value of exports, and in 2011 the deficit amounted to EUR 40.7 billion. In 2011, the great majority of imports were metal ores, with a share of 44%. Other products to record a large share of imports include vegetable fats and oils and oilseeds.

The USA was the major supplier of EU imports until 2004 when Brazil took over. Canada, Indonesia and Russia are the other main partner countries. EU exports in raw materials are relatively low as they make up less than 3% of total exports. As is the case for imports, metal ores are by far the most traded products.

Energy products

The main goods of energy products (SITC Section 3) are crude oil, refined petroleum products, coal, gas and electric current.

The EU is dependent on imports of energy products. This has led to a structural trade deficit, which reached a record level of EUR 388.6 billion in 2008. The value of imports closely follows the price of crude oil. EU imports remained fairly stable from 2000 to 2004, then rose strongly from 2005 to 2008, and again from 2010 to 2011.

The most imported goods are petroleum and petroleum products, mainly crude oil. Most of the remaining falls to gas and coal. The major energy providers for the EU are Russia and Norway, which made up about 40% of the imports in 2011. Algeria, Saudi Arabia and Nigeria also have relevant shares of EU energy imports.

The majority of EU exports are refined petroleum products. The biggest destination country is the USA, which accounts for about one fifth of total exports.

Data sources and availability

EU data come from [Eurostat](#) 's [COMEXT](#) database. COMEXT is the Eurostat reference database for international trade. It provides access not only to both recent and historical data from the EU [Member States](#) but also to statistics of a significant number of third countries. International trade aggregated and detailed statistics disseminated from Eurostat website are compiled from COMEXT data according to a monthly process. Because COMEXT is updated on a daily basis, data published on the website may differ from data stored in COMEXT in case of recent revisions.

EU data are compiled according to community guidelines and may, therefore, differ from national data published by Member States. Statistics on extra-EU trade are calculated as the sum of trade of each of the 27 Member States with countries outside the EU. In other words, the EU is considered as a single trading entity and trade flows are measured into and out of the area, but not within it.

Context

The EU is the world's biggest importer and exporter of agricultural products. Europe imports mostly basic agricultural commodities, but its exports are based on high-quality farm products and other processed agricultural products. Recognising the crucial role that agriculture plays in many developing countries, the EU has granted extensive market access to agricultural imports from developing countries. The European Union, due to the characteristics of the European industrial base, is highly dependent on imports of raw materials for its [competitiveness](#) and for its economic development. An increase in worldwide demand in raw materials in the future is expected; this increase will be largely due to economic growth in emerging economies. The European Union is also dependent on imports of energy from other countries. One of the key priorities is therefore to run a strategic international energy policy which leads to stable and secure supply routes.

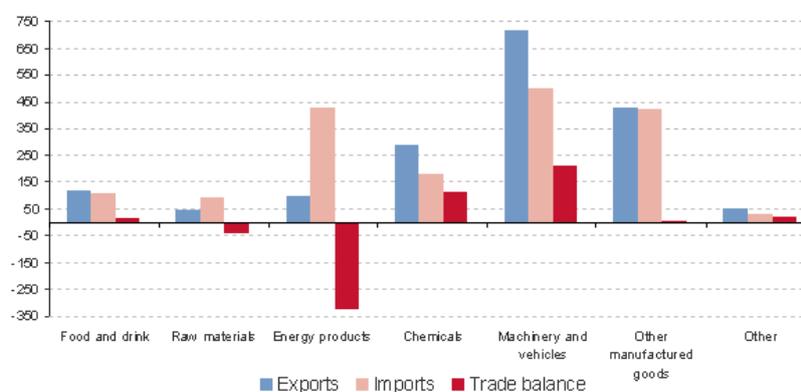

Figure 2: Euro area trade by product, 2011 (bn EUR)Source: Eurostat (TET00066)

The aim of this article is to provide an overview of the main characteristics of the [extra-euro area](#) trade in goods. All the series between 2000 and 2011 have been recalculated to include all the 17 members of the [euro area](#) (EA-17).

Main statistical findings

In 2011, extra-euro area (EA-17) trade increased to EUR 3480 billion from EUR 3089 billion in 2010, corresponding to a growth of 12.7%. EA-17 [imports](#) rose by 12.5% and [exports](#) by 12.8%. The EA-17 [trade balance](#) went from a [deficit](#) of EUR 15 billion in 2010 to a [deficit](#) of EUR 11 billion in 2011.

In 2011, the United Kingdom was the leading partner for extra-EA-17 exports, accounting for 12.3% of all exports, followed by the United States. China led for imports with 12.4% of total EA-17 imports, followed by the United Kingdom, the United States and Russia.

Both import and export trade were dominated by machinery and vehicles, followed by 'other manufactured goods'. In 2011, machinery and vehicles made up 41.5% of EA-17 exports and 31.2% of EA-17 imports.

Euro area trade by main partners

Over the whole period 2000-2011, the United Kingdom was the leading trading partner for extra EA-17 trade, followed by the United States. For EA-17, there was always a positive trade balance with both countries. In 2011, the United Kingdom accounted for 11% of all extra EA-17 trade and the United States for 10%. China was the third most important trading partner in 2011, only marginally behind the United States and Russia was fourth with 6%.

Every year over the period, the United Kingdom was the leading trading partner for extra EA-17 exports, with an increase in trade value of 13% between 2000 and 2011. The United States was second every year with an increase over the same period of 14%.

EA-17 trade with China increased by 347% between 2000 and 2011, with imports always significantly higher than exports. By 2007, China had overtaken the United Kingdom and the United States to become the leading trading partner for extra EA-17 imports and has remained in that position since. In 2011, EA-17 trade with China totalled EUR 332 billion, of which EUR 217 billion were imports. The United Kingdom was the second most important trading partner for EA-17 imports in 2011. In spite of a fall of 2% over the period 2000-2011, the United States was third and Russia was fourth.

EA-17 trade with Russia grew by 251% over the period, with imports always higher than exports. In 2011, EA-17 trade with Russia totalled EUR 219 billion, of which EUR 139 billion were imports. The United Kingdom, the United States, China and Russia together accounted for 36% of all extra-EA-17 trade in 2011.

Euro area trade by product

By far the most important [trade group](#) for both extra EA-17 imports and exports was machinery and vehicles, with a trade value in 2011 of EUR 1212 billion. EUR 712 billion were exports which represented 41% of the value of all extra EA-17 exports in 2011. Within that group, exports of road vehicles in 2011, with an increase of 15% on 2010, amounted to EUR 189 billion.

EA-17 imports of machinery and vehicles were dominated by electrical machinery which increased by 28% between 2000 and 2011 and amounted to EUR 107 billion in 2011. In spite of a fall in 2009, 2011 imports were 17% higher than in 2008.

In 2011, the second most important trading group for extra EA-17 trade was other manufactured goods, with trading values amounting to EUR 842 billion, of which EUR 423 billion were imports. Import trade was dominated by articles of apparel and clothing accessories (EUR 65 billion), miscellaneous manufactured articles (EUR 58 billion), and professional, scientific and controlling instruments and apparatus (EUR 32 billion). Imports of all these categories fell in 2009 but recovered in both 2010 and 2011. Export trade for other manufactured goods was dominated by miscellaneous manufactured articles (EUR 57 billion) and professional, scientific and controlling instruments and apparatus (EUR 45 billion). Looking at the product groups that showed a trade deficit for extra EA-17 in 2011, total trade in energy products amounted to EUR 522 billion of which EUR 425 billion were imports. The dominant imports were petroleum and petroleum products amounting to EUR 322 billion, which represented 18% of the value of all EA-17 imports in 2011 and an increase of 29% on 2010. Total trade in raw materials in 2011 amounted to EUR 134 billion of which EUR 89 billion were imports. The most imported products in this group were metalliferous ores and metal scrap, with an increase of 23% in 2011 to reach EUR 38 billion.

Data sources and availability

EU data comes from Eurostat's COMEXT database. COMEXT is the Eurostat reference database for international trade. It provides access not only to both recent and historical data from the EU Member States but also to statistics of a significant number of third countries. International trade aggregated and detailed statistics disseminated from Eurostat website are compiled from COMEXT data according to a monthly process. Because COMEXT is updated on a daily basis, data published on the website may differ from data stored in COMEXT in case of recent revisions.

EU data are compiled according to community guidelines and may, therefore, differ from national data published by Member States. Statistics on extra-euro area trade are calculated as the sum of trade of each of the euro area Member States with countries outside the euro area (including EU Members which are not in the euro area). In other words, the euro area is considered as a single trading entity and trade flows are measured into and out of the area, but not within it.

Context

The euro area is a large and open trading bloc. This makes doing business in euro an attractive proposition for other trading nations, which can access a large market using one currency. Euro area companies also benefit because they can export and import in the global economy while paying, and being paid, in euro, reducing the risk of losses caused by global currency fluctuations.

International trade by enterprise characteristics

Data from September 2012. Most recent data: Further Eurostat information, Main tables and Database .

This article takes a look at recent [European Union \(EU\)](#) international trade statistics from a very specific angle: the characteristics of the [enterprises](#) actively engaged in [importing](#) and [exporting](#) .

International trade statistics play a vital role in the assessment of every economy. Combining them with additional information from other sources, particularly business statistics, significantly enriches them, providing a closer view of traders and their characteristics such as [size](#) , [sector of economic activity](#) or level of concentration. This allows for a deeper analysis of the impact of trade on [employment](#) , production and [value added](#) , essential in a globalised world where economies are increasingly interconnected.

Table 5: Total Extra-EU imports and exports by economic activity and enterprise size, 2010Source: Eurostat Easy Comext – Table Trade by activity and enterprise size-class

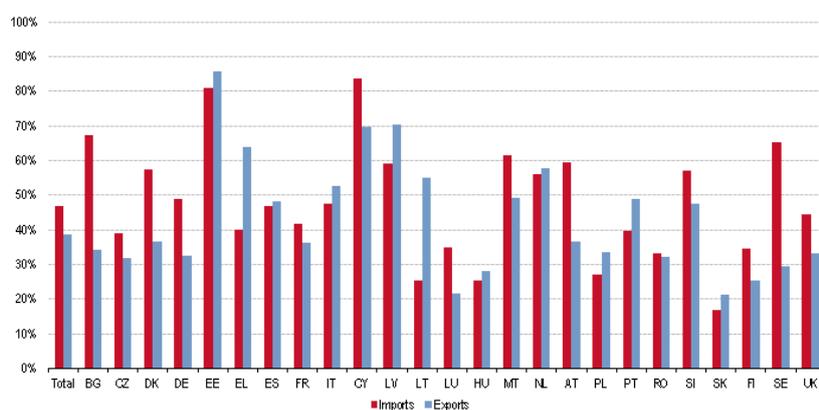

Figure 8: Extra-EU trade: share of SMEs in imports and exports (excluding enterprises in 'unknown' size-class), 2010(% in EUR)Source: Eurostat Easy Comext – Table Trade by activity and enterprise size-class

The main findings presented in this section focus on both [intra-](#) and [extra-EU](#) trade by economic activity and employment size class.

Small and medium-sized enterprises in intra-EU trade

SMEs are a significant driver of intra-EU trade

Intra-EU trade by size classes is one of the most important statistical indicators on trade by enterprise characteristics. In 2010, [small and medium sized enterprises \(SMEs\)](#) accounted for a considerable share of total intra-EU trade. Indeed, SMEs (0-249 employees) stood for 55% of trade value for [arrivals](#) (imports from another [EU Member State](#)) and 47% of trade value in [dispatches](#) (exports to another EU Member State). For all Member States, except Cyprus, the contribution of SMEs to arrivals was larger than to dispatches¹⁶⁷(see Figure 1).

[Small enterprises](#) (0-49 employees) were responsible for almost 32% of the value of arrivals, while the share of [medium-sized enterprises](#) (50-249 employees) was established at around 24%. In the Trade sector, SMEs were responsible for 72% of the value of arrivals, whereas [large enterprises](#) stood for 65% of the arrivals value in the Industry sector (see Table 1).

Focusing on total trade value for dispatches, the role of large enterprises is more significant. Small enterprises accounted for only 26% of the trade value, medium sized enterprises for 22% and large enterprises for the remaining 53%. While in the Trade sector, SMEs accounted for lion's share in the value of dispatches with 79%, the opposite applies in the Industry sector, with large enterprises standing for 68% of the total value dispatched.

Large enterprises in intra-EU trade

Small amount in absolute number but important share in value

Large enterprises made up only 2% of the enterprises having received arrivals from other EU Member States while their share in trade value amounted to around 44%. On the opposite, although small enterprises made up 93% of the enterprises receiving arrivals, their share in trade value was only 32%. Medium sized enterprises represented a moderate share in the number of enterprises (close to 5%) but they contributed more significantly to the value of arrivals (24%) (see Figure 2 and Figure 3).

Focusing on dispatches, the contribution of large enterprises to total value was even higher than for arrivals (Figure 4 and Figure 5). While large enterprises represented only 2% of the enterprises recording dispatches in 2010, they stood for nearly 53% of the trade value registered for dispatches. Small enterprises accounted to a lesser extent to dispatches than to arrivals, making up 89% of enterprises but accounting for only 26% of the dispatches value. Medium sized enterprises accounted for the remaining 9% of the enterprises and more than

¹⁶⁷Share calculated excluding enterprises in 'unknown' size-class.

21% of the trade value.

Intra-EU trade at country level

Significant disparities at country level in trade by enterprise size-classes

Drilling down at country level also shows a great disparity in the pattern applying when considering countries' total (see Table 2). There is a strong concentration of arrivals in trade values on large enterprises in Hungary, France, Germany, Czech Republic and the United Kingdom, the only countries where these large enterprises stood for more than half of the total arrivals. In contrast, SMEs accounted for more than three quarters of the value of arrivals in Latvia, Estonia, Lithuania, Cyprus and Poland (unknown size-class excluded).

In Finland, large enterprises were responsible for the lion's share of dispatches value (70% of the total value in 2010). On the other hand, SMEs dominated the value of dispatches in Cyprus and Latvia, both registering shares in total trade of more than 80% (see Table 3).

Intra-EU trade by economic activity sector

Trade sector is predominant for arrivals in number of enterprises

Focusing on enterprises activities at countries' total level, Industry and Trade sectors account for the majority of intra-EU trade compared to other sectors, both in terms of trade value and number of enterprises (see Figure 7). In 2010, the Industry sector contributed significantly more than the Trade sector to total intra-EU trade value: for arrivals, intra-EU trade was rather equally distributed between the Trade sector (46%) and the Industry sector (41%), while dispatches were principally driven by the Industry sector, which accounted for almost two-thirds (64%) of the total trade.

The number of enterprises involved in arrivals was unequally shared across the various sectors: while Trade represented a share of 45%, Industry accounted for only 18%. On the other hand, the number of enterprises involved in dispatches was more equally distributed between Industry (30%), Trade (40%) and the other sectors (30%).

The number of enterprises involved in intra-EU trade also differs significantly among Member States (see Table 4). Considering arrivals, the number of enterprises in the Trade sector exceeded those in the Industry sector for all Member States. For dispatches, the picture looks different with five countries (namely Italy, Poland, Portugal, Romania and Slovenia) registering more enterprises in the Industry sector than in the Trade sector.

Independently of the number of enterprises, the contribution of Industry and Trade sectors to intra-EU trade values also vary considerably among Member States. For arrivals, trade values are driven by Industry in six countries only: Czech Republic, Germany, Hungary, Poland, Romania and Slovakia. For dispatches, the Industry sector is predominant for trade values in all of the Member States, with three exceptions (namely Cyprus, Latvia and the Netherlands).

Extra-EU trade

Extra-EU trade accounted for around half of the total intra-EU trade

In absolute terms, extra-EU trade accounted for nearly half of the total intra-EU trade, for both number of enterprises and trade value (for both imports and exports).

Concerning the extra-EU trade, SMEs (0-249 employees) were responsible for nearly 47% of the value of imports, while the large enterprises (250+ employees) were responsible for the remaining 53%. In the Trade sector, SMEs were responsible for 69% of the value of imports, whereas large enterprises stood for almost 76% of the value of imports in the Industry sector (see Table 5).

When looking on total trade value for exports, the role of large enterprises is even more significant. Small

enterprises accounted for almost 21% of the trade value, medium sized enterprises for 18% and large enterprises for more than 61%. While in the Trade sector, SMEs accounted for lion's share in the value of exports with 77%, the opposite applies in the Industry sector, with large enterprises standing for more than 74% of the total value exported.

Extra-EU trade at country level

Large enterprise taking over more than half of the extra-EU trade

Extra-EU trade by size classes is an important statistical indicator on trade by enterprise characteristics. In 2010, large enterprises accounted for a considerable share of total extra-EU trade. Indeed, large enterprises accounted for 53% of trade value for imports and 61% of trade value in exports, while SMEs stood for the remaining 47% of trade value for imports and only 39% of trade value in exports (see Figure 8).

While for intra-EU trade, almost all countries had a higher contribution of SMEs to imports than to exports, the situation appears more balanced for extra-EU trade, with eleven countries registering a higher contribution of SMEs to exports.

The highest share of imports for SMEs was recorded by Cyprus (84%), followed by Estonia (81%) and Bulgaria (67%), while the highest share of exports was recorded by Estonia (86%), followed by Latvia and Cyprus (70%).

When referring to large enterprises, the highest shares of imports were recorded by Slovakia (83%), Hungary (75%) and Lithuania (74%), while the highest shares of exports were recorded by Slovakia (79%), Luxembourg (78%) and Finland (75%).

On the other side, the lowest share of imports and exports for SMEs was recorded by Slovakia (17% and 21% respectively). For large enterprises, the lowest share of imports was recorded by Cyprus (16%) while the lowest share of exports was recorded by Estonia (14%).

Total trade balance

SMEs recorded trade deficit in almost all Member States

Total **trade balance** by enterprise size also shows a clear disparity between SMEs and large enterprises, with SMEs experiencing a trade deficit in almost all countries in 2010, except for two countries: Italy and the Netherlands. On the other hand, larger enterprises recorded trade surpluses in most EU Member States, the most significant surplus being registered by far in Germany (see Figure 6).

The United Kingdom, France and Poland recorded the most significant deficits for SMEs, while for large enterprises the most significant deficit was recorded by the United Kingdom, Spain and the Netherlands. Italy was the sole country recording surpluses for both SMEs and large enterprises.

Data sources and availability

Reporting of international trade statistics by enterprise characteristics consists in a data collection independent from the monthly trade statistics. This data collection has been included in the revised Intrastat (respectively Extrastat) Regulations published in 2009 that came into force for the reference year 2009 (respectively 2010) onwards.

- Intrastat Regulation: Regulation (EC) No 222/2009 of the European Parliament and of the Council of 11 March 2009 amending Regulation (EC) No 638/2004 on Community statistics relating to the trading of goods between Member States.

- Extrastat Regulation: Regulation (EC) No 471/2009 of the European Parliament and of the Council of 6 May 2009 on Community statistics relating to international trade with non-member countries and repealing Council Regulation (EC) No 1172/95.

Until the reference year 2008, Member States were asked to compile specific indicators linking international trade data and business register information on a voluntary basis.

Data are disseminated once having ensured an accurate data quality and confidentiality issues are removed.

The compilation of trade flows by enterprise characteristics is based on linking micro data on intra- and extra-EU trade with structural information from business registers. The trade value of each trader, by product code and partner country, is combined with the main enterprise characteristics (economic activity and number of employees) retrieved from the business registers. Only aggregated results (e.g. no micro data) are provided to [Eurostat](#).

It should be noted that, in matching business registers with trade registers, some countries show high numbers of unmatched enterprises for arrivals and dispatches. However, this does not influence the trade values to any greater extent (by 8% on average for arrivals and 9% on average for dispatches). It is assumed that most of unmatched enterprises are SMEs. Moreover, when compiling international trade statistics by enterprise characteristics, the information on the size of the enterprises cannot always be allocated: in such case, the enterprises are classified in the “Unknown” size-class category. For intra-EU trade, this category represented 12% of the trade value and 13% of the number of enterprises for arrivals, as well as 15% of the trade value and 14% of the number of enterprises for dispatches. For extra-EU trade, it represented 17% of the trade value and 23% of the number of enterprises for imports, as well as 13% of the trade value and 18% of the number of enterprises for exports (2010 data). In order not to bias the results presented, all the size-class shares mentioned in this article exclude enterprises for which the size-class is unknown.

Definitions

Number of enterprises

The number of enterprises consists in a count of the number of enterprises involved in trade during at least a part of the reference period. For intra-EU trade, [VAT](#) data are used to estimate the number of traders and trade value of the smallest traders which are exempted from Intrastat reporting. These traders account for a very limited share of the trade value – at most 3% of the total value by flow – but in terms of number of enterprises they consist in the majority.

Number of employees

The number of employees is defined as those persons who work for an employer and who have a contract of employment and receive compensation in the form of wages, salaries, fees, gratuities, piecework pay or remuneration in kind.

SMEs

Small and medium sized enterprises are defined only according to their number of employees (enterprises with less than 250 employees); the exact definition of SMEs uses also turnover and balance sheet as criteria.

Trade balance

Trade balance presented in Figure 6 has been calculated as the difference between dispatches and arrivals reported by each country for total trade (intra- and extra-EU trade).

Classifications

Enterprises are classified according to the Statistical Classification of Economic Activities in the European Community, Rev. 2 ([NACE Rev. 2](#)). For detailed information, please refer to ‘Ramon’, Eurostat’s Classification Server: <http://ec.europa.eu/eurostat/ramon>

Business registers

For the reference year 2010, Regulation (EC) No 177/2008 of the European Parliament and the Council of 20 February 2008, establishing a common framework for Statistical Business Registers was the legal basis for business registers.

Statistical unit

The **statistical unit** to be used is the enterprise which is defined in the Council Regulation (EEC N° 696/93) as the smallest combination of legal units that is an organisational unit producing goods or services, which benefits from a certain degree of autonomy in decision-making, especially for the allocation of its current resources. Trade data that are generally collected and registered by declaring unit (identified by VAT code in intra-EU trade and by customs identification code in extra-EU trade) must be connected to characteristics available in the Business Register for the whole enterprise concerned.

Reporting countries

Until the reference year 2008, the data were collected annually on voluntary basis. The following countries have provided 2010 data: Bulgaria (BG), Czech Republic (CZ), Denmark (DK), Germany (DE), Estonia (EE), Greece (EL), Spain (ES), France (FR), Italy (IT), Cyprus (CY), Latvia (LV), Lithuania (LT), Luxembourg (LU), Hungary (HU), Malta (MT), the Netherlands (NL), Austria (AT), Poland (PL), Portugal (PT), Romania (RO), Slovenia (SI), Slovakia (SK), Finland (FI), Sweden (SE) and the United Kingdom (UK).

Country-specific notes

- “ **Countries** ’ total” refers to the aggregate of all countries that have provided data in 2010.
- Greece: Number of enterprises does not include traders which are exempted from Intrastat reporting.
- Lithuania: for arrivals data, the 2009 data are confidential for two size-classes (namely “50-249 employees” and “250 or more employees” both for the trade value and the number of enterprises).

Data availability

The figures presented in this article have all been taken from Eurostat’s Easy COMEXT dissemination database (<http://epp.eurostat.ec.europa.eu/newxtweb/>) and reflect the state of data availability as of 14th September 2012.

Within the traditional international trade database (Easy Comext), tables present data on international trade by enterprise characteristics from the reference year 2005 onwards. Data are available according to NACE Rev 1.1 for data until the reference year 2007 and according to NACE Rev 2 for data for the reference year 2008 onwards.

Context

International trade statistics play a vital role in the assessment of every economy. Combined with additional information on characteristics of enterprises involved in international trade, such as the size and the sector of economic activity, trade data are significantly enhanced. Generally speaking, trade statistics show goods movements between countries by good categories. However, they do not provide explicit information on the businesses which are behind these trade flows. In a globalised world where economies are increasingly interconnected, it is more and more important to know traders and their characteristics. Answering this question requires linking trade statistics with other sources, and particularly with business statistics, which describe the structure and evaluation of the activities of businesses.

‘International trade by enterprise characteristics’ is a new statistical domain, which unlike traditional trade statistics, aims at describing the structure of trade by characteristics of the trading enterprises, for instance by their economic activities, their size or concentration of trade. It is based on linking trade micro-data with business register information, allowing a deeper analysis of the impact of trade on employment, production and value added.

Statistics on trade by enterprise characteristics are compiled by linking intra- and extra-EU trade micro-data with business register data, and are available for trade value and number of enterprises for five indicators.

- **Trade by economic activity and enterprise size class** : trade by activity sector and employment size class shows the contributions of economic activities and size classes (measured in terms of number of employees) to total trade. This allows analysing the impact of external trade on employment and estimating the importance of small and medium-sized enterprises.
- **Concentration of trade by economic activity** : external trade being typically concentrated on a few enterprises, this indicator shows the share of the total trade accounted for by the top 5, 10, 20, etc. enterprises.
- **Trade by partner country and economic activity** : trade by partner countries shows how many enterprises were trading with certain partner countries or country zones, and the value they accounted for. This enables to identify most typical exports or imports markets.
- **Trade by number of partner countries and economic activity** : trade by number of partner countries shows how geographically diversified the exports markets are. For imports, it shows the number of countries from which goods are imported.
- **Trade by commodity and economic activity** : trade by commodity and activity sector allocates the trade of each commodity to the activity of the trading enterprise. This shows which sectors were involved in trading of each product group.

From the reference year 2008 onwards, the activity sector is broken down by NACE Rev. 2 division (2-digit level) for sections C (Manufacturing) and G (Trade) and by section level for other activities. The size-classes in terms of number of employees are: 0-9, 10-49, 50-249, 250 or more and Unknown. These indicators are available separately for intra- and extra-EU trade.

Confidentiality is applied in the statistics disseminated to ensure that it is not possible to identify an enterprise or a trader.

Figure 9: Main imports, EU-27, 2006 and 2011(% share of extra EU-27 imports) - Source: Eurostat (tet00061)

This article discusses the development of the [European Union's \(EU\)](#) international trade in goods. It considers the EU's share in world [import](#) and [export](#) markets, [intra-EU](#) trade, the EU's main trading partners, and the EU's most widely traded product categories.

The [EU-27](#) accounts for around one sixth of the world's trade in goods. The value of international trade in goods significantly exceeds that of services (by about three times), reflecting the nature of some services which makes them harder to move across borders.

Main statistical findings

EU-27 international trade in goods with the rest of the world (the sum of [extra-EU](#) exports and imports) was valued at EUR 3267 467 million in 2011 – see Figure 1; as such, trade activity for the EU-27 registered record levels for both exports and imports. In comparison with a year before, total trade in goods for the EU-27 increased by EUR 379939 million in 2011.

After experiencing a sharp fall in the level of exports and imports of goods in 2009, the EU-27 saw its exports rise to a record level of EUR 1553 923 million in 2011, an increase of 14.5% compared with the year before; this was largely driven by a rising level of exports of machinery and transport equipment and other manufactured goods. Imports of goods rose by 11.9% to be valued at EUR 1713 544 million, with the largest gains recorded for imports of mineral fuels and lubricant products and raw materials.

Germany remained by far the largest player in relation to extra EU-27 trade in 2011, contributing 27.7% of the EU-27's exports of goods to non-member countries and accounting for almost one fifth (19.2%) of the EU-27's imports – see Table 3. The next three largest exporters of goods, the United Kingdom (11.5%), France (10.7%) and Italy (10.6%) remained the same as in 2010 and were the only other Member States to account for a double-digit share of EU-27 exports. The United Kingdom (14.5%), the Netherlands (13.4%) and Italy (10.9%) followed Germany as the largest importers of goods from non-member countries; the relatively high share for the Netherlands can, at least in part, be explained by the considerable amount of goods that flow into the EU through Rotterdam – the EU's leading sea port. The largest extra EU-27 trade surplus in goods, valued at EUR 102217 million, was recorded for Germany, followed by Ireland (EUR 23649 million) and Sweden (EUR

18839 million).

Trade in goods between EU Member States (intra-EU trade) was valued – in terms of dispatches – at EUR 2804 131 million in 2011 – see Table 4. This was almost twice the level recorded for exports from the EU-27 to non-member countries (extra-EU trade). The importance of the EU's internal market was underlined by the fact that intra-EU trade of goods was higher than extra-EU trade in each EU Member State, with the exception of the United Kingdom (see Figure 5). The proportion of total trade in goods that was accounted for by intra-EU and extra-EU flows varied considerably across the Member States, reflecting to some degree historical ties and geographical location. The highest shares of intra-EU trade (about 80%) were recorded for Luxembourg, the Czech Republic and Slovakia, with this ratio falling to 51.2% in Greece and 49.4% in the United Kingdom.

Intra EU-27 trade – measured by dispatches – increased by 10.4% across the EU-27 between 2010 and 2011; this was a lower rate of increase than that recorded for extra-EU exports (which rose by 14.5%). Considering arrivals and dispatches together, the biggest increases in intra-EU trade between 2010 and 2011 were registered for Estonia (33.5%), Latvia (32.3%), Lithuania (28.2%) and Bulgaria (27.7%), while Greece (-2.4%) and Cyprus (-0.3%) were the only Member States to record reductions.

Analysis of main trading partners

Between 2010 and 2011, EU-27 exports of goods to all of its major trading partners increased. The highest growth rate was recorded for exports to Switzerland and Russia (up 26.2% and 25.9% respectively), while exports to the United States grew more slowly (up 7.6%) – see Table 5. However, the United States remained, by far, the most important destination for goods exported from the EU-27 in 2011 (see Figure 6), although the share of EU-27 exports destined for the United States fell from 27.8% of the total in 2001 to 16.8% by 2011. In value terms, the most important EU-27 exports to the United States in 2011 included machinery and transport equipment. The same group of products was also the main export category to China, which was the third most important destination market for EU-27 exports of goods in 2011 (8.8% of the EU-27 total), just after Switzerland (9.0%).

On the import side, the EU-27 saw an increase in the level of its imports of goods from all of its major trading partners between 2010 and 2011, except for imports from South Korea, which fell by 8.4%. China remained the most important supplier of goods imported into the EU-27 in 2011, even though the 3.5% growth in imports from China between 2010 and 2011 was the lowest growth rate in the last decade, aside from a contraction in 2009 during the financial and economic crisis. EU-27 imports from Russia rose by 24.4% and, as a result, Russia replaced the United States as the second biggest supplier of goods into the EU-27 in 2011. Imports from Russia were dominated by a 31.6% increase in the level of imports of mineral fuels and lubricant products, which made up four fifths (78.9%) of all the EU-27's imports from Russia in 2011.

Analysis of main product groups

Sharp increases in the level of exports outside the EU-27 were reported for all major product groups in 2011. The highest growth rate for EU-27 exports in 2011 was recorded for exports of mineral fuels and lubricant products, which reached the record value of about EUR 100000 million.

Imports of all major product groups also rose between 2010 and 2011, except for machinery and transport equipment, where there was little change in the level of EU-27 imports. As a result, this category was replaced by mineral fuels and lubricant products as the product group with the highest value of imports, following a substantial expansion (up 27.5% in 2011) in imports of mineral fuels and lubricant products into the EU-27. Almost one third (32.3%) of the EU-27's imports of mineral fuels and lubricant products in 2011 came from Russia, followed by Norway (12.3%) and Algeria (5.5%).

The EU-27's [trade deficit](#) of EUR 159622 million in 2011 was driven by the sizeable deficit in relation to mineral fuels and lubricant products, which stood at EUR 388594 million. This was offset by [trade surpluses](#) of EUR 208657 million for machinery and transport equipment, and EUR 99869 million for chemical and related products.

Data sources and availability

Statistics on the international trade of goods measure the value and quantity of goods traded between Member States of the EU (known as intra-EU trade) and goods traded by EU Member States with non-member countries (known as extra-EU trade). These statistics are the official source of information about imports, exports and the trade balance in the EU, its Member States and the [euro area](#) .

Statistics are published for each declaring country with respect to each partner country, for several product classifications. One of the most commonly used product classifications is the [Standard international trade classification \(SITC Rev. 4\)](#) of the [United Nations \(UN\)](#) ; this allows a comparison of international trade statistics to be made on a worldwide basis.

In extra-EU trade statistics, the data shown for the EU-27 treat this entity as a single trading block. In other words, the data for exports relate only to those exports from the EU-27 that leave the trading block and are destined for the rest of the world, while extra-EU imports relate to imports from the rest of the world (non-member countries) coming into the EU-27. In contrast, when reporting data for individual Member States, international trade flows are generally presented in terms of world trade flows (including both intra-EU and extra-EU partners).

Definitions for extra-EU trade flows are as follows:

- imports are goods which enter the statistical territory of the EU from a non-member country and are placed under the customs procedure for free circulation (as a general rule goods intended for consumption), inward processing, or processing under customs control (goods for working, processing), either immediately or after a period in a customs warehouse;
- exports are goods which leave the statistical territory of the EU for a non-member country after being placed under the customs procedure for exports (definitive export), outward processing, or re-exportation following either inward processing or processing under customs control.

Statistics on trade with non-member countries do not, therefore, include goods in transit or those placed under a customs procedure for bonded warehousing or temporary entry (for fairs, exhibitions, tests, etc.), nor do they include re-export following entry under one of these procedures.

Statistics on trade between the Member States (intra-EU trade) cover the arrivals and dispatches of goods recorded by each Member State. Arrivals and dispatches are defined as follows:

- arrivals are goods in free circulation within the EU which enter the statistical territory of a given Member State;
- dispatches are goods in free circulation within the EU which leave the statistical territory of a given Member State to enter another Member State.

Customs records are the traditional source of statistical data on trade in goods. The beginning of the [single market](#) on 1 January 1993, with its removal of customs formalities between Member States, made it necessary to adopt a new data collection system, Intrastat, as the basis for statistics on intra-EU trade. In the Intrastat system, statistical data are collected directly from trade operators – who are requested to send monthly declarations to their national statistical administration.

The statistical values of extra-EU trade and intra-EU trade are recorded at their free-on-board (FOB) value for exports/dispatches and their cost, insurance and freight (CIF) value for imports/arrivals. The values reported comprise only those subsidiary costs (freight and insurance) which relate, for exports/dispatches, to the journey within the territory of the Member State from which the goods are exported/dispatched and, for imports/arrivals, to the journey outside the territory of the Member State into which the goods are imported/enter.

Context

Statistics on the international trade of goods are used extensively by decision makers at an international, EU and national level. Businesses may use international trade data to carry out market research and define their

commercial strategy. International trade statistics are also used by EU institutions in their preparation of multilateral and bilateral trade negotiations, for defining and implementing anti-dumping policies, for the purposes of macro-economic and monetary policies, and in evaluating the progress of the single market, or the integration of European economies.

The development of trade can be an opportunity for economic growth. The EU has a common trade policy, whereby the [European Commission](#) negotiates trade agreements and represents the EU's interests on behalf of its 27 Member States. The European Commission consults Member States through an advisory committee which discusses the full range of trade policy issues affecting the EU including multilateral, bilateral and unilateral instruments. As such, trade policy is an exclusive power of the EU – so only the EU, and not individual Member States, can legislate on trade matters and conclude international trade agreements. This scope extends beyond trade in goods, to cover [trade in services](#) , intellectual property and [foreign direct investment](#) .

Globally, multilateral trade issues are dealt with under the auspices of the [World Trade Organisation \(WTO\)](#) . Its membership covers 157 countries (as of August 2012), with several candidate members in the process of joining. The WTO sets the global rules for trade, provides a forum for trade negotiations, and for settling disputes between members. The European Commission negotiates with its WTO partners and participated in the latest round of WTO multilateral trade negotiations, known as the Doha Development Agenda (DDA). However, having missed deadlines to conclude these talks in 2005 and again in 2006, the Doha round of talks broke down again at a WTO meeting in July 2008. At the time of writing, the future of the Doha round is uncertain.

International trade in medicinal and pharmaceutical products

Data from October 2010. Most recent data: Further Eurostat information, Main tables and Database .

The European Union (EU) was by far the major world trader in medicinal and pharmaceutical products (SITC division 54) in 2009, with total trade amounting to EUR 123.3 billion. Exports made up 65% of this trade. The United States occupied the second position for trade in these products, at some distance, with trade worth EUR 74.9 billion.

Over the period 2000-2009, the United States was the main trading partner for extra-EU (EU-27) exports of these products. Both export and import trade more than doubled over the period and, in 2009, the USA accounted for 35% of all extra-EU-27 trade.

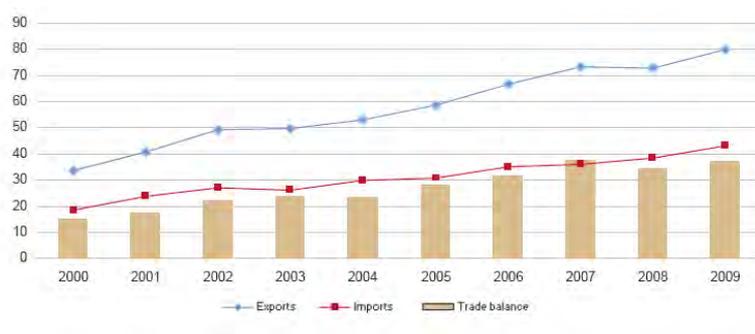

Figure 1: Evolution of Extra-EU-27 trade in medicinal and pharmaceutical products, 2000-2009, (billion euro)

Table 2: Extra-EU-27 trade in medicinal and pharmaceutical products, by Member State (million euro)

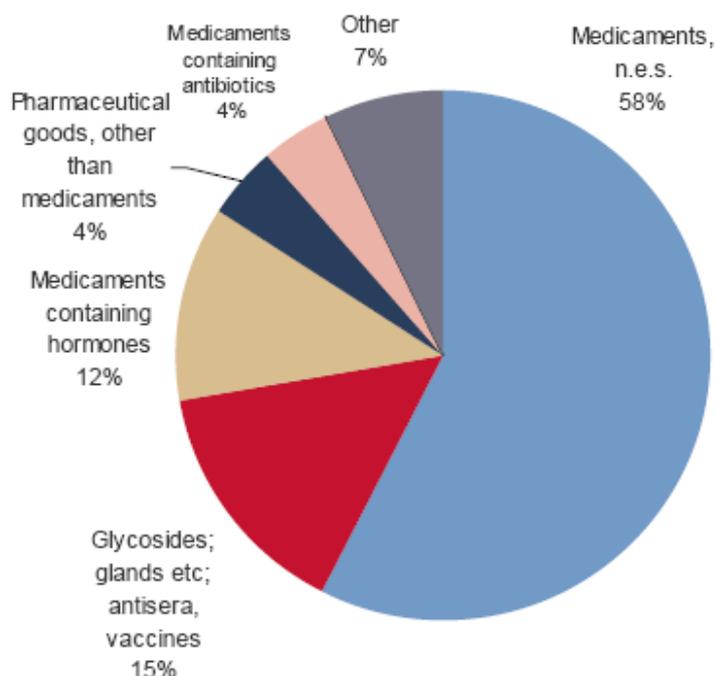

Figure 3: Extra-EU-27 exports of medicinal and pharmaceutical products, by SITC subgroup, 2009 (% of value)

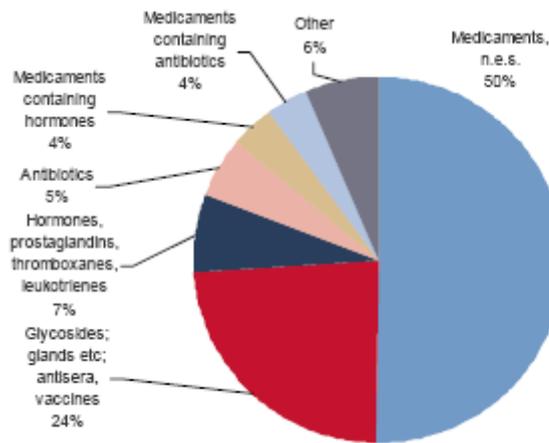

Figure 4: Extra-EU-27 imports of medicinal and pharmaceutical products, by SITC subgroup, 2009 (% of value)

Switzerland was the main trading partner for imports, with a growth of 174% over the period 2000-2009. In 2009, Switzerland accounted for more than a fifth of all extra-EU-27 trade in these products.

Main statistical findings

EU-27 trade in medicinal and pharmaceutical products rose by 11% in 2009, in spite of the global economic crisis

Increases in both exports and imports

In 2009, contrary to global economic trends, extra-EU-27 trade in medicinal and pharmaceutical products grew for both exports and imports. Exports, which had dropped slightly in 2008, rose by 10%, while imports rose by 13%.

The total value of extra-EU-27 trade in these products more than doubled over the period 2000- 2009 from EUR 52.1 billion in 2000 to EUR 123.3 billion in 2009.

Trade was dominated by exports, which were almost the double of the value of imports for every year from 2000 to 2009. The EU-27 [trade surplus](#) in this category varied between EUR 15.3 billion in 2000 and EUR 37.3 billion in 2007.

Increased trade with the United States and Switzerland in 2009

The United States stands out as the EU-27's main trading partner every year over the period 2000-2009.

The value of EU-27 exports to the United States increased by almost 150% between 2000 and 2007, before dropping slightly in 2008. In 2009, values increased by 10%.

Switzerland was the second largest EU-27 export partner in 2009, albeit at only about a third of the level of exports to the United States.

In 2009, EU-27 exports of medicines (SITC 542), including veterinary medicines, amounted to EUR 59.6 billion and accounted for 74% of all EU-27 exports of medicinal and pharmaceutical products. This was made up by a wide variety of medicaments. Exports of medicinal and pharmaceutical products other than medicaments (SITC 541) amounted to EUR 20.5 billion; the largest single product group was antisera, blood fractions, modified immunological products and vaccines (SITC 54163), with 13% of total exports.

Switzerland and the United States were the largest EU-27 trade partners also on the import side, together accounting for 79% of the imports of these products in 2009. EU-27 imports from Switzerland increased by 174% over the period from 2000 to 2009; by 2007 Switzerland had overtaken the United States as the leading import partner.

With 58%, medicines made up a larger share of imports than other medicinal and pharmaceutical products. However, also for imports the largest single product group was antisera, blood fractions, modified immunological products and vaccines, making up almost 24% of the imports of these products.

Strong growth for Belgium for both exports and imports

Amongst the EU-27 Member States, the five largest exporters of medicinal and pharmaceutical products together accounted for 72% of these exports in 2009. The leaders were Germany and Belgium who together accounted for 36%.

The United States was the most important export partner for all of these five leading Member States in 2009; together, they accounted for 87% of all extra-EU-27 exports of medicinal and pharmaceutical products to the United States.

For imports, the picture was more differentiated. The six largest EU-27 importers together accounted for three quarters of the extra-EU-27 imports of these products in 2009. Germany was the leading importer among the Member States.

Switzerland was the most important import partner for Germany, France and Italy, while the United States was the most important import partner for Belgium, the Netherlands and the United Kingdom.

Data sources and availability

EU data are compiled according to community guidelines and may therefore differ from national data published by Member States (see [External trade aggregated data](#) - ESMS file).

Data source : Eurostat's free dissemination database; for non EU-data (Figure 2) [United Nations](#) ' COM-TRADE database. A code (such as 'DS_018995') is inserted as part of the source. This hyperlinked code allows the reader to easily access the most recent data on the [Eurostat](#) website. The data on the website is frequently updated and may also be more detailed or have a different measurement unit.

Reporting countries : EU-27: Belgium, Bulgaria, the Czech Republic, Denmark, Germany, Estonia, Ireland, Greece, Spain, France, Italy, Cyprus Latvia, Lithuania, Luxembourg, Hungary, Malta, the Netherlands, Austria, Poland, Portugal, Romania, Slovenia, Slovakia, Finland, Sweden and the United Kingdom.

The "Rotterdam effect": Extra-EU imports of some Member States (e.g. Netherlands), and therefore their trade deficit, are overvalued because of the so-called 'Rotterdam effect'. Goods destined for the rest of the EU arrive in their ports and, according to Community rules, are declared as imports by the Member State where these goods are released for free circulation. This in turn reduces the extra-EU imports to those Member States to which the goods are re-exported, as these shipments are recorded, for Community statistics, as arrivals from the Member State where these goods are released for free circulation, rather than imports from an extra-EU partner.

Commodities classification :

Division 54 'Medicinal and pharmaceutical products' of the [Standard international trade classification](#) revision 4 (SITC Rev. 4), is made up of the sub-groups:

- 5411 'Provitamins and vitamins (not put up as medicaments)';
- 5413 'Antibiotics (not put up as medicaments)';

- 5414 'Vegetable alkaloids (not put up as medicaments)';
- 5415 'Hormones, prostaglandins, thromboxanes and leukotrienes';
- 5416 'Glycosides; glands or other organs; antisera, vaccines';
- 5419 'Pharmaceutical goods, other than medicaments';
- 5421 'Medicaments containing antibiotics';
- 5422 'Medicaments containing hormones, etc., but not antibiotics';
- 5423 'Medicaments containing alkaloids, but not containing hormones etc. or antibiotics';
- 5429 'Medicaments not elsewhere specified'.

Context

Pharmaceutical products are among the most important products within the chemicals sector(SITC section 5). Besides machinery and vehicles, the chemicals sector is the only product group where the EU posts a trade surplus. The surplus reached EUR 83.1 billion in 2009.

The pharmaceutical industry is one of the largest sectors in the European Union, accounting for 3.5% of total manufacturing production. Pharmaceutical companies in the EU employ approximately 633,000 employees.

The most common trade impediments faced by pharmaceutical exporters are a range of burdensome and costly registration, licensing and certification procedures. The EU aims to redress these through its bilateral trade agreements or by tackling individual barriers as part of its market access partnership.

International trade in motor cars

Data from August 2012. Most recent data: Further Eurostat information, Main tables and Database .

The car industry is of prime importance to the economy of the [European Union \(EU\)](#) and plays a major role in international trade. New and used motor cars accounted for about 6% of the total value of all extra-EU exports in 2011, but less than 2% of the total value of all extra-EU imports .

This article describes the development of trade in motor cars both within the EU (intra-EU trade) and outside of the EU (extra-EU trade). It shows that the USA, China and Japan are the EU's main trading partners while among EU Member States Germany is the leading exporter of cars.

Table 2: Extra EU-27 trade of motor vehicles, by category, 2011(EUR million) - Source: Comext

In 2011, the EU exported motor cars worth EUR 93.8 billion. Imports in that same year amounted to roughly a quarter of that value (EUR 24.2 billion), giving an EU trade surplus of EUR 69.6 billion.

The value of extra-EU exports of motor cars increased by an average 25% per year between 2009 and 2011. During the same period, extra-EU imports grew at a much slower pace, at an average 3% per year.

In 2011, the United States remained the EU's main partner for motor car exports (21% of the total), just ahead of China (19%). Together with Russia (8%) and Switzerland (7%) they counted for more than half of the EU market. Since 2009, EU motor car exports to China and Russia have grown particularly rapidly (respectively +47% and +40% per year).

Over a quarter (28%) of all extra-EU motor car imports in 2011 came from Japan, followed by the United States (20%), South Korea and Turkey (both 14%). Among the major partners for imports, Japan is the only one to show a decrease of trade during the latest years.

Within the broader 'road vehicles' category (which includes lorries, road tractors, motorcycles, trailers and motor-vehicle parts), motor cars represented 60% of extra-EU exports and 47% of extra-EU imports in 2011. Parts and accessories of motor vehicles had a share of 23% and 29% respectively.

Germany was responsible for over half (60%) of total extra-EU motor car exports; apart from Germany, the United Kingdom was the only Member State to show a positive trade balance of noticeable size.

At the same time, Germany was also the biggest importer of motor cars in 2011; about one third of the total value of extra-EU imports can be ascribed to Germany, well ahead of Belgium, Italy and the United Kingdom.

Trading partners

In 2011, the USA remained the number one partner for extra-EU exports (see Figure 2) with a share of 21% (close to EUR 20 billion). During the latest years China overtook Russia and Switzerland to become the second export market for EU cars (19% share) due to a particularly strong growth. Starting from a low level in absolute terms, exports to China displayed an impressive average growth rate between 2000 and 2011 of 48% per year.

In 2011, over a quarter (28%) of extra-EU motor car imports came from Japan (see Figure 3), well ahead of the USA (20%) and South Korea (14%). Imports from the USA and from Mexico have been growing at an average 16% per year, between 2009 and 2011. Imports from South Africa increased even faster during the same period (+24% per year on average). The strongest relative growth was registered for imports from Morocco (imports quintupled between 2009 and 2011) but absolute values remained relatively low.

Contribution of Member States

Looking at the 2011 exports of motor cars by the individual Member States (see Table 1), Germany alone was responsible for well over half (60%) of the EU total. The United Kingdom, ranking second, registered about a fifth of the German export value with a share of 13%. In relative terms, i.e. compared to their total extra-EU trade, exports of motor cars from countries such as Slovakia, the Czech Republic and Lithuania were fairly significant.

The majority of EU Member States showed a considerable increase of motor cars exports between 2009 and 2011: exports grew particularly fast in Cyprus and Bulgaria, although their shares remain of minor importance. Conversely, the value of car exports showed a reduction in only 3 Member States over the same period, Greece (-33%), Finland (-13%) and Malta (-11%), while exports from Ireland remained nearly stable.

With a value of EUR 7.7 billion, Germany's share in total EU car imports was the most significant (32% of the EU total), followed by Belgium and Italy, both with shares above 10%. Looking at the development between 2009 and 2011, German imports displayed a continuous annual increase (11% on average), with a sharp rise between 2010 and 2011. Luxembourg stands out as the Member State where imports have experienced the most noticeable relative increase (34% per year on average), followed by the Czech Republic (24%).

Ten Member States featured trade deficits in 2011, the largest were registered by the Netherlands, Italy and Slovenia, with values ranging between EUR 400 million and EUR 800 million.

Road vehicles

'Road vehicles' - cars and other motor vehicles, as well as cycles - represented 10% (EUR 155.9 billion) of total extra-EU exports and 3% (EUR 51.4 billion) of total extra-EU imports in 2011 (see Table 2). All subcategories of 'road vehicles' generated trade surpluses except 'motor cycles and cycles', which accumulated a deficit of EUR 3.7 billion.

'Motor cars and other motor vehicles' is the main category of 'road vehicles', with a share of around 60% of exports and 77% of imports. 'Parts and accessories of motor vehicles' follows with shares of around 25%.

In relative terms, two sectors are noteworthy: 'motor cycles and cycles' are mainly imported (11% of road vehicle imports), whereas 'road vehicles, not elsewhere specified', such as road tractors are mainly exported (4% of road vehicles exports).

Data sources and availability

Products of the road vehicles sector are defined according to the fourth revision of the [Standard international trade classification](#). They include divisions for 781 motor cars and other motor vehicles for transporting people; 782 motor vehicles for the transport of goods and special-purpose motor vehicles; 783 road vehicles, not elsewhere specified (tractors, etc); 784 parts and accessories of motor vehicles; 785 motor cycles and cycles, motorized and non-motorized; invalid carriages, as well as 786 trailers and semi-trailers.

EU data are compiled according to EU guidelines and may, therefore, differ from the national data published by the Member States.

Context

The automobile industry remains of prime importance for the EU, producing about a quarter of the world total of cars. The industry accounts for 5% of employment in the EU and is an important contributor to many of the EU's national economies. In Germany, for example, the industry's share in manufacturing as a whole is close to 20%, according to the [European Automobile Manufacturers' Association](#).

Trade in new and used motor cars accounts for a substantial part of the EU total, with close to 6% of the total value of all extra-EU exports in 2011.

The industry has suffered from the financial crisis which started in 2008 and is also under pressure from environmental regulation to curb tailpipe emissions.

(1) EU-27, extra-EU flows; euro area, extra-euro area flows; Member States and other countries, flows with the rest of the world.

(2) 2010.

Source: Eurostat (online data codes: bop_q_gdp, bop_q_c and tec00001)

Table 1: Trade in goods and services, 2011 (1)(% of GDP) - Source: Eurostat (bop_q_gdp), (bop_q_c) and (tec00001)

The [European Union \(EU\)](#) has a common trade policy, often referred to as the common commercial policy. In other words, the EU acts as a single entity on trade issues, including issues related to the [World Trade Organisation \(WTO\)](#) . In these cases, the [European Commission](#) negotiates trade agreements and represents Europe's interests on behalf of the EU Member States.

Main statistical findings

Having been disrupted by the global financial and economic crisis in 2009, there was a return to progressively more trade integration for the EU-27 in 2010 and 2011 – see Figure 1. The crisis had a considerable impact on the international exchange of goods and services in 2009 – however, this was relatively short-lived and the level of trade integration for goods and services bounced back in 2010 to levels that were above those recorded in 2008.

The average value of EU-27 [credits](#) and [debits](#) relative to [gross domestic product \(GDP\)](#) corresponded to 12.9% of GDP in 2011 for goods, up from a relative low of 9.8% in 2009. The level of trade integration for services was less pronounced (than for goods) and the pace of recovery following the financial and economic crisis was less rapid. Nevertheless, the average value of credits and debits rose to 4.2% of GDP in 2011, up from a relative low of 3.8% in 2009. The latest data for 2011 shows that the relative importance of trade integration for both goods and services within the EU-27 economy was at its highest level ever in 2011; these figures confirm that the recovery from the crisis was more rapid for international trade than for GDP.

The EU-27 trade deficit for goods and services (see Table 1) was equivalent to -0.2% of GDP in 2011, a smaller deficit than in the United States (-3.7%) or Japan (-0.7%). The EU-27's deficit in 2011 was composed of a surplus for services (0.9% of GDP) and a slightly larger deficit for goods (-1.1%).

Among the Member States, the combined trade balance for goods and services in 2011 was positive in 14 Member States in 2011. Positive balances exceeded 10% of GDP only in Ireland (21.7%) and Luxembourg (41.3%); in the case of Ireland this was due to a particularly large surplus for goods, while for Luxembourg it was due to a large surplus for services. The two largest trade deficits for goods and services were recorded in Romania (-5.2% of GDP) and Greece (-5.9%); in both cases the deficit was driven by a relatively large deficit for goods.

Data sources and availability

Within the EU, there are two main sources of trade statistics. One is international trade in goods statistics, providing information on trade in merchandise goods, collected on the basis of customs and Intrastat declarations. This provides highly detailed information on the value and quantity of [international trade in goods](#) as regards the type of commodity. The second main source is balance of payments statistics (BoP), which register all the transactions of an economy with the rest of the world. The current account of the BoP provides information on international trade in goods and services, as well as income (from employment and investment) and current transfers. For all these transactions, the BoP registers the value of exports (credits) and imports (debits), this source is used to present information on [international trade in services](#) .

Trade integration of goods and services is defined as the average value of debits and credits (summed and divided by two), presented in relation to GDP: the terms credits and debits are used for international trade in services which can roughly be considered to be equivalent to exports and imports for international trade in goods. This indicator is calculated for both goods and services, based on balance of payments data; if the values increase over time, then the reporting territory became more integrated within the international economy. It is normal that smaller countries will display a higher degree of trade integration, as they are more likely to import a range of goods and services that are not produced within their domestic markets.

Context

The [EU Treaty \(TEU\)](#) (also called the Treaty of Maastricht) establishes the overall aims and objectives of the EU's trade policy: Article 3 sets out the general aims, including a competitive social market economy, aimed at full employment and social progress. Article 206 of the [Treaty on the functioning of the Union \(TFEU\)](#) explains how the common commercial policy must operate in principle: 'to contribute, in the common interest, to the harmonious development of world trade, the progressive abolition of restrictions on international trade and on foreign direct investment, and the lowering of customs and other barriers'. Article 207 of the TFEU sets out the scope, instruments and decision-making procedures, while Article 218 establishes the current inter-institutional procedure for the conclusion of international agreements, principally by the [Council](#) .

The EU's trade policy aims to make the EU competitive in foreign markets. Being an open economy, the

EU seeks to secure improved market access for its industries, services and investments, and to enforce the rules of free and fair trade. A coordinated trade policy takes on even greater importance in an era of globalisation, where economies and borders have opened up, leading to an increase in trade and capital movements, and the spread of information, knowledge and technology, often accompanied by deregulation. The economic impact of globalisation on the EU is felt through trade in goods and services, as well as through financial flows and the movement of persons linked to cross-border economic activity.

In August 2012, Russia became a member of the WTO. This development has the potential to provide a boost to the European economy, as Russia is the EU's third largest trading partner. Russia is expected to lower its import duties, limit its export duties and grant greater access to its markets, as well as introducing a range of other measures.

The EU in the world - international trade

Data from June - July 2012. Most recent data: Further Eurostat information, Database .

This article is part of a [set of statistical articles](#) based on the Eurostat publication *The EU in the world 2013* .

The article focuses on the international trade in the [European Union \(EU\)](#) and in the 15 non-EU countries from the [Group of Twenty \(G20\)](#) . It covers key trade statistics - international trade in goods and balance of payments - and gives an insight into the European economy in comparison with the major economies in the rest of the world, especially with the EU's counterparts in the so-called [Triad](#) , the US and Japan, and with the [BRIC](#) countries Brazil, Russia, India and China (or [BRICS](#) if South-Africa is also included).

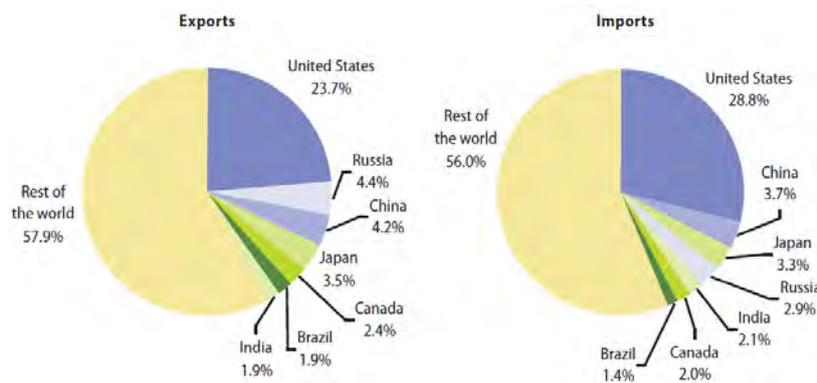

Figure 6: Selected G20 trading partners for EU-27 exports and imports of services, 2011 (% share of extra EU-27 flows) Source: Eurostat (bop_its_ybk)

Main statistical findings

Trade in goods and services (% of GDP)

For goods, the EU27 recorded a trade deficit that was 1.1% of its GDP

The level of international trade relative to overall economic activity (the ratio of traded goods and services to GDP) may be expected to be considerably higher for relatively small countries that are more integrated in the global economy as a result of not producing a full range of goods and services, as can be seen, for example, with Saudi Arabia and South Korea in Figure 1. By contrast, the United States reported the second lowest ratio of international trade (average of exports and imports) of goods and services to GDP (15.9%) in 2011 among the G20 members, higher only than that in Brazil (12.1%). While trade in goods dominates international trade, trade in services has grown strongly: trade in services was equivalent to 7.0% or more of GDP in India and Saudi Arabia and reached 8.7% of GDP in South Korea.

Relative to GDP, Saudi Arabia recorded by far the largest international trade surplus (goods and services combined) in 2011 among the G20 members, its surplus in goods outweighing its services deficit by an amount equivalent to 30.9% of GDP; Russia (8.7%) and China (4.0%, 2010 data) recorded the next largest surpluses. At the other end of the scale, Turkey's goods deficit was nearly five times as large as its services surplus, resulting in an overall deficit equivalent to 9.2% of GDP, larger (in relative terms) than the deficits recorded for India (5.3%, 2010 data) and the United States (3.7%). For goods, the EU27 recorded a trade deficit that was 1.1% of its GDP, slightly larger than the 0.9% of GDP trade surplus recorded for services.

Trade in goods

Close to three fifths of all EU27 exports of goods in 2011 were destined for G20 members, most notably the United States (17.0% share), China (8.9%) and Russia (7.1%)

In 2007 China overtook the United States to become the second largest **exporter** of goods among the G20 members, behind the EU27. Despite the strong growth in Chinese exports, the EU27's exports of goods in 2011 remained higher – see Figure 2. By contrast, Chinese imports of goods were notably lower than **imports** into either the EU27 or the United States. Together, the EU27, China and the United States accounted for 40.0% of global exports of goods in 2011 and 42.8% of global imports.

The EU27 ran a **trade deficit** for goods equal to EUR 155.8 billion in 2011; this was the second largest deficit among the G20 members, behind that recorded for the United States (EUR 563.8 billion). Table 2 shows the flows and balance of trade in goods for the EU27 with the other G20 members. In 2011 the EU27 had relatively large trade deficits with China and Russia, while its largest surplus was with the United States. Between 2001 and 2011 the EU27's goods trade balance with India, South Africa and Turkey developed from a deficit into a surplus, whereas this situation was reversed with Saudi Arabia.

The two parts of Figure 3 analyse the importance of the other G20 members for the EU27's trade in goods. Close to three fifths of all EU27 exports of goods in 2011 were destined for G20 members, most notably the United States (17.0% share), China (8.9%) and Russia (7.1%); the EU27's main export market outside of the G20 was Switzerland which was the destination for 7.9% of the EU27's exports. Collectively the G20 members provided just over three fifths of the EU27's imports of goods, with China (17.3%), Russia (11.8%) and the United States (10.9%) the main countries of origin; Norway (5.5%) and Switzerland (5.4%) provided similar shares of the EU27's imports.

Figures 4 and 5 show the reverse situation, namely the importance of the EU27 as a trading partner for the other G20 members in terms of the trade in goods. Nearly half of all goods exported from Russia and Turkey were destined for the EU27 in 2011, whereas this was the case for less than one tenth of goods exported from Canada, Australia or Mexico. The EU27 was the source of more than one fifth of all goods imported into Russia, Turkey, South Africa, Saudi Arabia (2010 data) and Brazil, while the EU27 supplied less than one tenth of all goods imported into Japan, South Korea and Indonesia.

Trade in services

The EU27 is the world's largest exporter and importer of services with a surplus of EUR 92.4 billion in 2010

The EU27 is the world's largest exporter and importer of services with a surplus of EUR 92.4 billion in 2010 and provisional data show that this rose to EUR 109.1 billion in 2011. Although the United States recorded somewhat lower levels of exports and imports of services than the EU27, its trade surplus for services was higher in 2010, valued at EUR 107.4 billion. Among the other G20 countries, only India and Turkey reported trade surpluses for services, while the largest deficits were registered for Saudi Arabia, Brazil and Russia. Comparing trade flows for 2010 with those for 2000, India, China, Russia and Brazil all reported that exports and imports of services had more than more than doubled (in current price terms).

A relatively high share of the EU27's trade in services was with the United States in 2010 and 2011 – although exports and imports were broadly in line with each other – resulting in a relatively small deficit in 2010 and small surplus in 2011. With the other G20 members listed in Table 4 (note that data is not available for those G20 members that are not shown) the EU27 had trade surpluses in services; between 2010 and 2011 the surpluses with Brazil, Canada, China, Japan and Russia increased, while the surplus with India contracted but remained positive.

The analysis of the EU27's trading partners shown in Figure 6 for services can be compared with a similar analysis for goods (see Figure 3). The importance of the United States as a trading partner for the EU27 for services is notably higher than it was for goods, whereas the reverse was true for China and Russia. Among countries outside of the G20, Switzerland was an important partner for trade in services as it was the destination for 13.0% of the EU27's exports of services and the origin of 11.4% of the EU27's imports of services, in both cases a larger share than Russia, China and Japan combined.

Data sources and availability

The statistical data were mainly extracted during June and July 2012.

The indicators are often compiled according to international – sometimes global – standards, for example, UN standards for national accounts and the IMF's standards for balance of payments statistics. Although most data are based on international concepts and definitions there may be certain discrepancies in the methods used to compile the data.

EU27 and euro area data

Almost all of the indicators presented for the EU27 and EA-17 aggregates have been drawn from Eurobase, Eurostat's online database. Eurobase is updated regularly, so there may be differences between data appearing in this publication and data that is subsequently downloaded. In exceptional cases some indicators for the EU have been extracted from international sources, for example, when values are expressed in purchasing power parities. Otherwise, European Commission sources have been used.

G20 countries from the rest of the world

For the 15 G20 countries that are not members of the EU, the data presented have generally been extracted from a range of international sources listed in the [Introduction](#). In a few cases the data available from these international sources have been supplemented by data for individual countries from national statistics authorities. For some of the indicators a range of international statistical sources are available, each with their own policies and practices concerning data management (for example, concerning data validation, correction of errors, estimation of missing data, and frequency of updating). In general, attempts have been made to use only one source for each indicator in order to provide a comparable analysis between the countries.

Context

Globalisation acquires a higher profile when it is measured by actual trade flows. There are two main sources of trade statistics: the first is international trade in goods which provides highly detailed information on the value and quantity of international trade; the second is balance of payments statistics which register all the transactions of an economy with the rest of the world. The current account of the balance of payments provides information on international trade in goods and services, as well as income (from employment and investment) and current transfers. For all these transactions, the balance of payments registers the value of exports (credits) and imports (debits).

Innovation and information society

Human resources in science and technology

Data from November 2011, most recent data: Further Eurostat information, Main tables and Database .

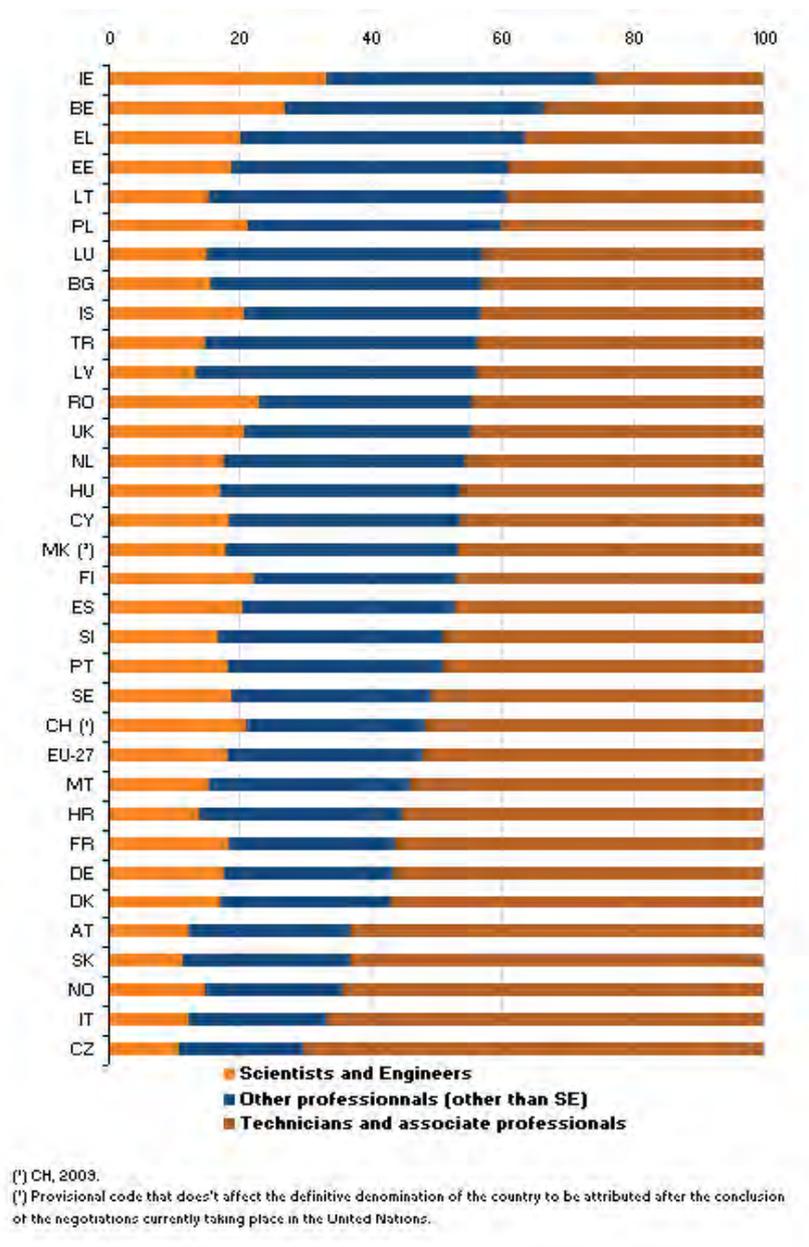

Figure 1: HRST by occupation, 2010 (%) Source: Eurostat (hrst_st_nocc)

This article provides information on [human resources in science and technology \(HRST\)](#) statistics which improve the understanding of the demand for and the supply of people with high qualifications in science and technology. They describe the current stock of HRST in the [European Union \(EU\)](#) , the [candidate countries](#) and [EFTA](#) countries. They also give information on the current and future supply of highly skilled people from universities and other education institutions into the HRST stocks.

Investment in research, development, education and skills constitutes a key policy area for the EU as these are elements essential to economic growth and to the development of a [knowledge-based economy](#) , leading to an increasing interest in the role and measurement of skills. In this context, the need to measure and analyse the most highly skilled part of the [labour force](#) has increased, both within the EU and internationally.

The HRST statistics focus on two main aspects:

- *stocks* , about the characteristics of the current labour force involved in science and technology;
- *flows* showing the job-to-job mobility and the inflow from [education](#) to the science and technology labour force; particular attention is paid to scientists and engineers, who are often the innovators at the centre of technology-led development.

Table 1: HRSTO women in manufacturing and services, 2010 Source: Eurostat (hrst_st_nsecsex2)

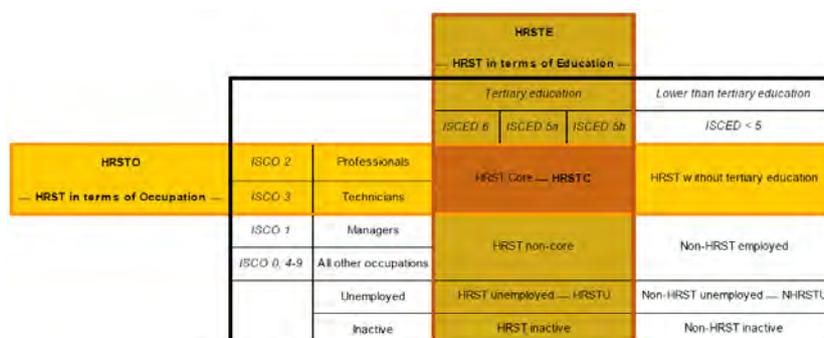

Figure 5: HRST categories

Professionals and technicians employed in science and technology occupations

Almost 62 million people in the EU were employed in science and technology occupations in 2010. This made up almost one-third of the total employed population. Four **Member States** (Germany, France, Italy and the United Kingdom) accounted for more than half of the 'professionals' (highly-qualified HRST employees). The same four Member States also counted for around 60% of the human resources in science and technology by occupation (HRSTO) employed as 'technicians' in the EU.

At EU level in 2010, the 'professionals' and the 'technicians' accounted for 48% and 52% respectively. However, there were large differences between Member States. Ireland, with 75%, reported by far the highest share of highly-qualified professionals amongst HRSTO. Other Member States with more than 60% professionals were Belgium (66%), Greece (64%), Estonia and Lithuania (61%) and Poland (60%). Among the sub-group of 'professionals' there is a special category of interest 'scientists and engineers', which includes persons employed in 'physical, mathematical and engineering' occupations as well as 'life science and health' occupations (see Figure 1).

In 2010, the share of scientists and engineers, in among the persons employed in science and technology occupations (HRSTO), was 18% in the EU as a whole. Again, Ireland (33%) and Belgium (27%) topped the list, well ahead of the other Member States. In absolute numbers, the largest group of scientists and engineers was found in Germany with approximately 2.3 million, followed by the United Kingdom, France, Spain, Poland and Italy. These Member States together employed 70% of all the scientists and engineers in the EU.

Within the professionals group, Ireland (45%) and Switzerland (43%) had the highest shares of scientists and engineers. However, many countries recorded shares of 40% or more, including France, Romania, Finland, Norway, Germany and Belgium.

Regional characteristics of highly-educated individuals in S&T occupations

The stock of human resources in science and technology can be used as an indicator of the development of the knowledge-based economy. The core group of HRST, the so-called 'HRST core', is made up of people who both have a university-level degree and are working in a science and technology occupation. The HRST core is central to the development of knowledge and technological innovation.

The HRST core category is normally concentrated in capitals and the regions around them, in regions with key universities and research institutions and as well as in regions where large enterprises have set up their headquarters and main research units. Regional data on the HRST core are available for the EU Member States, the candidate countries and the EFTA countries. In 2010, 14 of the 25 regions with the highest shares of HRST core in their labour force were capital regions (see Figure 2). The capital region of Norway, Oslo og Akershus, topped the list with 36% HRST core in its labour force. It was followed by Inner London and the Brabant Wallon region south of Brussels (with 33% and 32%), Luxembourg (31%) and the Danish capital Copenhagen (Hovedstaden, 30%).

A number of regions with key universities and research centres can also be found in the top list, including the Brabant Wallon and Vlaams-Brabant regions in Belgium, Utrecht in the Netherlands, Vestlandet and Trøndelag in Norway and País Vasco in Spain. The Nordic countries are well represented, with 7 of the 25 top regions; 4 of these are in Norway.

Senior human resources in science and technology

The EU population is getting older. This is also true for the human resources in science and technology. The senior HRST are amongst the most experienced and knowledgeable in the field of science and technology; their knowledge is important for driving research and innovation in Europe forwards.

In 2010 there were over 93 million people aged from 25 to 64 in the EU HRST. Of these 38 million were 'senior' HRST, i.e. between 45 and 64 years old. This corresponded to 41% of the HRST in the EU. The share of HRST aged 25–34 in the EU was 30%.

Among the Member States, Germany had the largest share of 'senior' HRST with 49%, combined with the

lowest share (23%) of the youngest HRST group (25–34 years old). Croatia, Finland, Estonia, Bulgaria, the Netherlands and Sweden have around 45% or more 'senior' HRST (see Figure 3). At the other end of the scale, Ireland (31%), Portugal (32%), Romania and Spain (both 33%) had the lowest shares of 'senior' HRST among the Member States. These first three above mentioned Member States also had a high share of HRST in the age group 25–34 years old, although the highest share among the Member States was recorded in Poland (42%). At the EU level, there were 28 million people aged 25–34 in the HRST category in 2010, corresponding to about 30% of the total HRST aged 25–64.

An interesting picture is revealed on close inspection of the candidate countries. Croatia, the Former Yugoslav Republic of Macedonia and Iceland are among the countries with the highest shares of 'senior' HRST and the lowest shares of the youngest HRST age group (25–34 years old). In fact, Croatia is the country with the largest share of 'senior' HRST (56%) among the candidate countries; at the same time, Croatia has the second lowest share of 'young' HRST (24%), a figure which falls closely behind Germany. In contrast, the country with both the lowest share of 'senior' HRST (24%) and the highest share of the youngest HRST (47%) is Turkey.

Women in science and technology

The [Europe 2020 strategy](#) aims to make the EU a smart, sustainable and inclusive economy that delivers high levels of employment, productivity and social cohesion. Innovation, as a motor for economic progress, is a key element of the strategy. Increasing the human resources employed in science and technology is part of the initiatives to strengthen innovation. In this context, it is vital to make better use of the resources and the qualifications of highly-skilled women in science and technological innovation. In most Member States, there are at least as many women as men in university level education, and the number of female doctorate students increases more rapidly than the number of male doctorate students.

When analysing the employment of human resources in science and technology in terms of occupation by [NUTS 1](#) regions, in 2010 the highest shares of women employed in science and technology occupations were found in the [Baltic Member States](#) and in one German region: Lithuania topped the list with 69%, followed by Estonia (68%), region Sachsen-Anhalt (66%) and Latvia (66%). High shares of women in science and technology jobs were found in the 'new' Member States in Central and Eastern Europe, as well as in the eastern part of Germany. The list of the top 20 regions includes Slovakia, all regions in both Poland and Bulgaria, 2 of 3 regions in Hungary, 4 of the 5 regions in former East Germany. The only candidate country (and at the same time the only EFTA country) to make the top 20 list was Iceland (see Figure 4).

In 2010, the vast majority of women in science and technology occupations were working in [services](#): this number was approximately 29 million, compared to only 2 million in manufacturing. Overall, women dominated science and technology employment in the services sector, with the exceptions of Luxembourg with 47%, Cyprus with 48% and Malta with 50%. In the rest of the EU Member States, there were more women than men in science and technology occupations in the services sector.

In the manufacturing sector, the situation is completely different. At EU level, women constituted only 29% of the HRSTO working in this sector were women. Estonia, Lithuania, Latvia and Iceland were the only countries to report a share of 50% or more female HRSTO employed in the manufacturing sector.

Data sources and availability

The data on stocks (workforce) and flows (job-to-job mobility) are obtained from the EU [Labour force survey](#). The data on education inflows are obtained from the [UNESCO / OECD / Eurostat](#) questionnaire on education. Both surveys are carried out by the national statistical institutes and the results forwarded to Eurostat.

Definitions

For producing HRST statistics, Eurostat uses harmonised concepts, methods and definitions according to the Manual on the Measurement of Human Resources devoted to Science and Technology, [the Canberra Manual](#), jointly written by OECD, UNESCO, the [International Labour Organization \(ILO\)](#) and Directorate General

for Research and Innovation and Eurostat of the [European Commission](#). The text was discussed at specialist workshops at the OECD and then submitted to the Group of National Experts on Science and Technology Indicators (NESTI). The Canberra manual is the fifth in the 'Frascati family' - a collection of NESTI documents.

In this manual, highly-skilled human resources are described as essential for the development and flow of knowledge and as forming the crucial link between technological progress and economic growth, social development and environmental well-being. Countries and international organizations highlighted the political and economical importance of a need for internationally comparable, harmonized and high quality data on human resources.

The data on stocks and flows (both job-to-job mobility and inflows from education) are the main statistics of HRST. Although the stocks and job-to-job mobility statistics have a different source than the education inflow to HRST, their methodologies are linked.

Human resources in science and technology (HRST) are defined as persons fulfilling at least one of the following two conditions (see Figure 5):

- human resources in terms of education: individuals who have successfully completed a university level education;
- human resources in terms of occupation: individuals who are employed in a science and technology occupation as 'Professionals' or 'Technicians and associate professionals'.

The group that fulfils both of these criteria is called the HRST core.

Stocks and job-to-job mobility

Data used on stocks and mobility of HRST are taken from Eurostat's Labour force survey database. The data on HRST stocks relate to the employment status, the occupation and the education of individuals. HRST stocks and flows statistics are broken down by gender, age, region, sector of economic activity, occupation, educational level, fields of education, nationality and country of birth. However, not all combinations are possible.

The analysis of HRST mobility casts light on two different aspects: the job-to-job mobility of employed HRST and the international mobility of the HRST core. Job-to-job mobility is defined as the movement of a person from one job to another from one year to the next. It does not include inflows into the labour market from unemployment or inactivity.

Education inflow

HRST education inflow data come from Eurostat's Education database. They are collected via the UNESCO/OECD/Eurostat (UOE) joint questionnaire on education. National statistical institutes or Ministries for Education compile the national data, in many cases taken from administrative registers.

The education inflow data give a good measure of the current and future supply of HRSTE. The inflows can be divided into specific groups, each providing a different focus; the annual data on actual inflows ('graduation'; i.e. students completing a university level study) and potential inflows ('participation'; i.e. students in higher education) from the education system into the HRST stocks.

Even though the official definition of HRST in the Canberra Manual contains 'S' and 'T', the definition is not restricted to science and technology in the strict sense. HRST by education covers all fields of study, i.e. anybody who successfully completed a tertiary level education.

Comparability of concepts and data

The statistics on the stock and mobility of human resources in science and technology (HRST) can be compared to and combined with Eurostat's Labour force survey statistics and part of the [high-tech statistics](#); they all

have the same source, the EU Labour force survey (LFS), and the processing errors are thought to be insignificant. However, users should pay close attention to concepts and definitions if they compare or combine HRST statistics with statistics from other domains and/or sources.

For example, 'Total HRST' should not be compared with total employment, as the total stock of HRST also covers unemployed and inactive HRST. If one needs to make such comparisons, one might use either the 'HRST in terms of occupation' or the 'HRST core' group sub-groups, or use a HRST table that is explicit in only containing HRST who are employed.

Comparability between HRST stock and mobility statistics and the HRST education inflow statistics should be done very carefully, as the original sources for these statistics have totally different methodology. For example, an HRST table that shows the field of education cannot be compared to a table showing employed HRST; only 'HRST in terms of education' contain the education dimension – not all employed HRST have a university level education.

Context

Europe 2020

Investment in research, development, education and skills is one of the European Union's central policy areas. These key areas are essential to economic growth and to the development of the knowledge-based economy. The Europe 2020 strategy sets out a vision of Europe's social market economy for the 21st century. It aims to turn the EU into a smart, sustainable and inclusive economy that delivers high levels of employment, productivity and social cohesion. Innovation is a motor for economic progress: it is therefore a key element of Europe 2020.

Europe 2020 puts forward three priorities that go together and reinforce each other:

- smart growth: developing an economy based on knowledge and innovation;
- sustainable growth: promoting a more resource efficient, greener and more competitive economy;
- inclusive growth: fostering a high-employment economy, delivering social and geographical cohesion.

Innovation Union

The European Commission has defined seven flagship initiatives to create progress under the Europe 2020 strategy. One of these is the "Innovation Union", supporting 'Smart growth'. The Innovation Union initiative improves the framework for research and innovation in the EU. It also improves the access to finance. The aim is to ensure that innovative ideas can be turned into products and services that create growth and jobs.

A key element of the Innovation Union is to complete the [European Research Area \(ERA\)](#) . ERA aims to increase the competitiveness of European research institutions by bringing them together and encouraging a more inclusive way of work. Increased mobility of knowledge workers and deeper co-operation among EU research institutions are central goals of ERA.

ERA should inspire the best talents to enter research careers in Europe and stimulate industry to invest more in European research. It enables European researchers to develop strong links with partners around the world, so that Europe benefits from the progress of knowledge worldwide, contributes to global development and takes a leading role in international initiatives to solve global issues.

However, there are still national and institutional barriers which limit the development of ERA. In 2008, the European Commission and the Member States launched new initiatives to develop ERA, including the 'Ljubljana Process' to improve the political governance of ERA. Several initiatives on specific areas have been initiated. These initiatives aim at establishing partnerships with Member States and business, universities and research organizations to develop the ERA in their specific field.

One of these five new initiatives intends to create a [European Partnership for Researchers for mobility and career development](#) . Improving the mobility of researchers will improve the flow of knowledge throughout Europe, balance demand and supply for researchers at the European level, help create centres of excellence and

improve the skills of researchers in Europe. Improving career prospects for researchers in Europe will stimulate more young people to choose a research career, help keep researchers in Europe and attract more talented non-European researchers.

Careers of doctorate holders

Data from the CDH 2009 voluntary data collection, most recent data: Further Eurostat information, Main tables and Database

Holders of doctorate degrees or other research qualifications are crucial to the creation, commercialization and dissemination of knowledge and to [innovation](#) . Until now, however, there has been little information about their careers and [labour market](#) mobility.

This article explains the statistics resulting from the international 'Survey on the careers of doctorate holders (CDH)', jointly carried out [Eurostat](#) , the [Organisation for Economic Co-operation and Development](#) (OECD) and [UNESCO](#) 's Institute for Statistics (UIS). The survey covers most of the Member States of the [European Union](#) (EU), of [EFTA](#) as well as some of the most important other members of the OECD, such as the United States and Australia.

From the CDH 2009 data collection, graduates after 1990

Personal characteristics of research qualification holders

In most countries, the percentage of men with research qualifications exceeds 60% of the total. Latvia has the highest share of women with research qualifications, and is actually the only country where women outnumber men in this category. Among younger age groups, there tends to be a higher share of women qualified to do research, as confirmed in the latest reports.

The age distribution varies considerably among countries. For several countries, the 35-44 age group is the largest; for others, the 35-44 and 45-54 groups are equally dominant. Overall, the population of 55 years or older accounts for only a small percentage in most countries with the exception of Latvia and Hungary.

Employment characteristics and work perception

Most identified doctorate holders were employed at the time of the survey. The share of unemployed doctorate holders is below or close to 2% in most countries. The share of **inactive** doctorate holders varies between the countries but does not exceed 5%. Significant percentages are noted in Latvia (5.9%) and Finland (7.6%).

More than half of the doctorate holders are employed as researchers in all countries. In several countries this percentage exceeds 75%.

Among employed researchers, the largest percentage is active in higher education. In some countries, the percentage exceeds 60%, most notably in Malta with 82.8%. Government appears to be the second choice for researchers, followed by the business enterprise sector. In the private non-profit sector, the percentage of employed researchers is below or close to 10% for all countries, except for the Netherlands (18.5%).

The data indicate that research qualification holders are employed in jobs related to their doctorate degree. In most of the countries, the respective share is higher than 60% and in particular, in Hungary exceeds 80%. Notable exception is Belgium, where only 40% of doctorate holders are employed in jobs related to their studies.

Job satisfaction

In almost all countries, most research qualification holders purport to be 'somewhat satisfied' with their salary. This group is followed by those who are 'somewhat dissatisfied'. The proportion of research qualification holders who are 'very dissatisfied' is rather low in the majority of countries, except for Hungary (24.5%).

A closer look at the data reveals that salary is one of the main reasons for which most research qualification holders are dissatisfied with their work, along with the lack of benefits and opportunities for advancement.

Reverse international mobility

Among research qualification holders, citizens of the reporting country, who have lived or stayed abroad in the past ten years, the majority lived in the European Union and a significant share in North America. Most of them moved back to their country of residence because of academic factors, family or personal reasons or due to other job related or economic factors.

Data sources and availability

The Careers of Doctorate Holders survey for the reference year 2006 (CDH 2006) was the first international, coordinated round of this data collection, and thus had a certain element of 'pilot exercise'. In total, 26 countries participated in the initial CDH 2006 survey, i.e. most of the Member States of the European Union (EU), of EFTA and some of the most important other members of the OECD, such as the United States and Australia. Reference year for the first CDH was 2006, although there were a few exceptions (three countries used 2005 and two countries 2007 as reference year).

In 2010, the CDH survey was carried out for a second time with reference to the 2009 data (CDH 2009) for most of the countries, and to 2008 data for four countries. The survey was again conducted in 26 countries, i.e. 16 EU Member States, 3 EU **Candidate countries**, 2 EFTA countries and 5 other OECD countries from the rest of the world.

Most of the countries carried out a dedicated survey on CDH, while others used data from the national **Labour**

force survey (LFS) or other register data. Countries that used either the LFS or administrative data or population census to derive CDH figures tended to supply limited data in the output tables. In contrast, data derived from dedicated surveys was very complete in respect to the requirements set by the three international organizations. In CDH 2009, the number of countries carrying out a dedicated survey was increased, and this improved the completeness of the output tables compared to the pilot exercise.

With regard to the data sources used for the CDH in both collections, countries used multiple sources to build their sampling frame. Where more than one source was used, there has been an effort to avoid overlap. These data sources cover special characteristics of the target population. For example, sources, such as R & D surveys or registers concerning employment/business/enterprises cover employed doctorate holders awarded either in the reporting country or abroad; sources such as databases of universities and national registers of doctorate holders cover doctorate holders awarded in the reporting country. The combination of sources complements the survey frames with recent doctorate holders that have not yet been noted in an official register.

Quality of data sources

The quality of the data sources and consequently the efficacy of the survey frame are vital for the complete coverage of the target population. According to the guidelines, the target population should have included all doctorate holders (citizens of the reporting country or citizens of foreign countries) awarded within the country and abroad and being resident (permanent or non-permanent) in the country on the reference date. Departures from these recommendations mainly result from insufficient sources of data, which fail to cover (fully or partly) all the sub-groups of doctorate holders resident in the country. The sub-categories that were mostly under-covered were: ISCED six graduates whose doctorates were awarded abroad, unemployed and inactive graduates, non-permanent residents and foreign citizens.

Data harmonization and quality control

As the national methods for collecting the data may vary between countries, reflecting the diversity of the national statistical systems, the CDH statistics have tried to harmonize this information and impose quality controls. The aim was to obtain high-quality results through a harmonized list of variables and indicators, together with their related definitions. Different countries are at different stages of the CDH statistics, in particular in reaching the final aim of full coverage of the target population. In a transition phase where countries seek to fully implement the methodological guidelines, incomplete coverage will have to be accepted to support their effort. However, this came at the expense of comparability of the data. In parallel with the work on analysis, quality control and publication of results from CDH 2006, the OECD's UIS and Eurostat are already preparing for the next round of the CDH survey. This next study will use 2009 as reference year but seek to improve the model questionnaire, the questionnaire manual and the methodological guidelines. These guidelines provide guidance on the target population, sampling frames, sampling design, etc., that should be respected in the national surveys in order to provide harmonised and comparable statistics.

Target population of CDH data

A common, harmonized definition of the target population has been critical for the usefulness of the CDH data. The countries supplying the information often use different national sources and surveys for both the sampling frame (i.e. the overview of research qualification holders from which a sample for the survey is drawn) and the statistics.

The total target population of the CDH statistics consists of all people with an education at ISCED 6 level (i.e. research qualification holders, mainly doctorate holders). These can be divided into national populations, considered the target populations of national surveys in each country. Many highly skilled people tend to work and contribute to society with their skills and knowledge at advanced ages. However, one of the main aims of the CDH statistics, i.e. the measuring of mobility and career path, is targeting relatively young research qualification holders.

In summary, the national target populations for the CDH survey consist of people who in the reference year:

- have an education at ISCED 6 level, obtained anywhere in the world;
- live (permanently or non-permanently) in the survey country;

- are 69 or younger.

With these definitions and the assumption that all countries conducted the survey according to the common methodological guidelines and with the same year, the whole population of doctorate holders and other research qualification holders living in those countries is covered, without any overlaps. The resulting statistics should, thus, be complete and fully comparable between all participating countries.

Context

Europe 2020

Investment in research, development, education and skills is one of the European Union's central policy areas. These key areas are essential to economic growth and to the development of the knowledge-based economy. The [Europe 2020 strategy](#) sets out a vision of Europe's social market economy for the 21st century. It aims to turn the EU into a smart, sustainable and inclusive economy that delivers high levels of employment, productivity and social cohesion. Innovation is a motor for economic progress: it is therefore a key element of Europe 2020.

Europe 2020 puts forward three priorities that go together and reinforce each other:

- smart growth: developing an economy based on knowledge and innovation;
- sustainable growth: promoting a more resource efficient, greener and more competitive economy;
- inclusive growth: fostering a high-employment economy, delivering social and geographical cohesion.

Innovation Union

The [European Commission](#) has defined seven flagship initiatives to create progress under the Europe 2020 strategy. One of these is the "Innovation Union", supporting 'Smart growth'. The Innovation Union initiative improves the framework for research and innovation in the EU. It also improves the access to finance. The aim is to ensure that innovative ideas can be turned into products and services that create growth and jobs.

A key element of the Innovation Union is to complete the [European research area \(ERA\)](#). ERA aims to increase the competitiveness of European research institutions by bringing them together and encouraging a more inclusive way of work. Increased mobility of knowledge workers and deeper co-operation among EU research institutions are central goals of ERA.

ERA should inspire the best talents to enter research careers in Europe and stimulate industry to invest more in European research. It enables European researchers to develop strong links with partners around the world, so that Europe benefits from the progress of knowledge worldwide, contributes to global development and takes a leading role in international initiatives to solve global issues.

However, there are still national and institutional barriers which limit the development of ERA. In 2008, the European Commission and the Member States launched new initiatives to develop ERA, including the 'Ljubljana Process' to improve the political governance of ERA. Several initiatives on specific areas have been initiated. These initiatives aim at establishing partnerships with Member States and business, universities and research organizations to develop the ERA in their specific field.

One of these five new initiatives intends to create a [European Partnership for Researchers for mobility and career development](#). Improving the mobility of researchers will improve the flow of knowledge throughout Europe, balance demand and supply for researchers at the European level, help create centres of excellence and improve the skills of researchers in Europe. Improving career prospects for researchers in Europe will stimulate more young people to choose a research career, help keep researchers in Europe and attract more talented non-European researchers.

Thus, in recent years the need to measure the career development and mobility of the highest-skilled segment of the labour force has increased, both within the EU and internationally.

Doctorate holders and other research qualification holders are not only the most qualified individuals in terms

of educational accomplishment, but also the only ones specifically trained to conduct research.

The CDH statistics try to answer questions about the international mobility of highly skilled workers, as frequently discussed under the headings of 'brain drain' / 'brain gain' / 'brain circulation'. In addition, these statistics address whether the quality and the number of research qualification holders educated correspond to labor market needs. Furthermore, the issue of whether the national labour markets remain the main frame for this highly skilled group is addressed. Other issues are how well the skills of the highest educated are used by society, as well as how attractive different careers are to the research qualification holders. The CDH statistics give policy makers a much stronger basis for addressing these issues.

High-tech statistics

Data from October 2011, most recent data: Further Eurostat information, Main tables and Database .

This article analyses data on [high-technology](#) or 'high-tech' sectors in the [European Union \(EU\)](#) and in some [EFTA](#) and [candidate countries](#) . Creating, exploiting and commercialising new technologies is essential in the global race for [competitiveness](#) and high-tech sectors and [enterprises](#) are key drivers of economic growth, [productivity](#) and [social protection](#) , and generally a source of high [value-added](#) and well-paid [employment](#) .

High-tech can be defined according to three different approaches:

- the *sector* approach looks at the high-tech manufacturing sector, medium high-tech manufacturing sector, and high-tech [knowledge-intensive service](#) sector, focusing on employment, and economic indicators as shown in Table 1;
- the *product* approach considers whether a product is high-tech or not and examines trade in high-tech products;
- the *patent* approach distinguishes high-tech patents from others and also defines what [biotechnology](#) patents are.

Economic statistics on high-tech

In 2008, the European Union had almost 50000 enterprises in high-tech manufacturing and 756000 in high-tech knowledge-intensive services (Table 1). High-tech manufacturers were most numerous in Germany, United Kingdom, Italy and France, all together accounting for around 55% of the high-tech sector in the EU. The United Kingdom displayed the greatest number of enterprises in the high-tech [knowledge-intensive services \(KIS\)](#) sector (144006), comprising almost one-fifth of the EU total, followed by Italy and Germany.

An interesting picture emerges when considering [turnover](#) ; Germany led the way in 2008, with a total turnover and value added almost twice as high as in the countries with comparable numbers of high tech manufacturers.

Germany's turnover represented almost one-fourth of EU total in 2008 rounded to EUR 128 billion in high-tech manufacturing, ahead of France (EUR 76 billion) and Italy (EUR 50 billion). The value added was distributed in 2008 in a similar way with the highest contribution of Germany close to EUR 41 billion, followed by France and United Kingdom (EUR 20 billion each).

Turning to the high-tech KIS sector, in 2008, the European Union had 756 thousand enterprises in high-tech knowledge-intensive services, 33% of which were registered in the United Kingdom and Italy with 144000 and 104000 respectively. However, what it is striking is that the turnover, production value and value added figures were practically twice as high in the United Kingdom as in Italy. One of the main reasons for this is the [size class of enterprises](#) and a prevailing share of [small and medium-sized enterprises \(SME\)](#) .

Employment in high-tech

In 2010, 34 million people were employed in the manufacturing sector in the [EU-27](#) , representing 15.9% of the total employment. Out of 34 million workers, 2.3 million were employed in high-tech manufacturing what equals to 1.1% of total employment. High-tech KIS sector in 2010 was more than double that of high-tech manufacturing and accounted for 2.7% of total employment. The shares of both manufacturing and services in the high-technology sectors in total employment varied considerably from one country to another. High-tech manufacturing shares ranged from 0.2% in Cyprus, 0.3% in Turkey, 0.4% in Portugal, Norway and Croatia to 3.1% in Ireland, 2.8% in Switzerland and Hungary, and 2.6% in Malta. Discrepancies in terms of the proportion of high-tech KIS in total employment were also observed across countries. The biggest share of more than 4% was recorded in Former Yugoslav Republic of Macedonia, Iceland, Sweden and Denmark, and the lowest below 1.9% was found in Portugal, Poland, Greece, Lithuania, Romania and Turkey. (see Table 2)

At the EU level, over the period 2008–2010, the number of employed persons in the manufacturing sector decreased by roughly 4.5% a year. The high-tech manufacturing recorded a little slower fall of 4.3% a year. This decrease in employment can be partially explained by the economical crisis in 2010 affecting numerous European countries. The impact of the crisis was also observed in the services sector which did not record any growth from 2008 to 2010, while up to 2008, this sector used to generate new jobs at the pace of 2% a year. At the same time, the high-technology services (KIS) showed a certain resistance to crisis and recorded a rise in the number of jobs at the level of 0.3% on average per year from 2008 to 2010. Some important differences emerged when comparing the employment change among countries with significant growth on the one hand, and equally significant decline on the other. Twenty-three out of thirty-three observed countries registered a fall in the employment in high-tech manufacturing in the period 2008–2010, with the biggest fall of 28% recorded in Cyprus and Croatia and 26% in Portugal. Growth in high-tech manufacturing was observed in the following five countries: Turkey (15%), Switzerland (3%), Denmark (1%), Slovenia (1%) and Estonia (0.2%). In high-tech KIS the loss was more moderate. Eleven countries registered a decline. The biggest job loss was reported in Malta (-16%), Cyprus (-10%) and the United Kingdom (-8%). The best performing countries in terms of growth of the employment in high-tech KIS were: Turkey (27%), Luxembourg (14%), Slovakia (10%), Belgium and Czech Republic (8%).

Table 2 compares also the percentages of women of both high-tech sectors with the respective total in manufacturing or services.

In the EU-27, women accounted for 29.6% of the employment in manufacturing and this share reached 39.2% in high-tech manufacturing. However, even if in general the shares of women were higher in high-tech manufacturing than in manufacturing, the gender balance in high-tech manufacturing was in favour to women (above 50% of all the employed) only in five countries: Portugal, Slovakia, Czech Republic, Slovenia and Hungary.

In contrast, high-tech KIS sector, as compared to total services sector, showed lower shares of women in all countries with the EU average of 30.8% in high-tech KIS and 54.4% in services. Moreover, in high-tech KIS none of the countries reached the gender balance. For high-tech KIS the lowest share was recorded in the Former Yugoslav Republic of Macedonia (10.5 %), the Netherlands (21.3%) and Turkey (23.4%). On the other hand, women were relatively strongly represented in Bulgaria (43.8%), Lithuania (38.6%) and Romania (36.0%). The reasons behind the lower female participation in high-tech KIS lay in the specificities of sectors included in that aggregate: Computer programming, Scientific research and development, Telecommunication, and corresponding occupations which apparently remain more popular among men.

Trade in high-tech products

Trade in high-tech products refers to the [import](#) and [export](#) of products identified as being of high-technology. The high-tech products are divided in 9 groups: 'Aerospace', 'Armament', 'Chemistry', 'Computer -office machines', 'Electrical machinery', 'Electronics - telecommunication', 'Non - electrical machinery', 'Pharmacy', 'Scientific instruments'. On the global level, the export value of high-tech products represented around 16% of all exports value in 2009. The two groups of products together, i.e. 'Electronics – telecommunication' and 'Computer – office machines' accounted for 63% of high-tech exports worldwide (Figure 1). 'Scientific instruments', 'Aerospace' and 'Pharmacy' jointly mounted up to for one fourth of global high-tech exports. By contrast, 'Chemistry', 'Non-electrical machinery', 'Electrical machinery' and 'Armament' summed up to a mere 10% of total high-tech exports.

In 2009, the three world leaders in terms of exports of high-tech products were China (21.6%), the EU (15.9%) and the United States (13.5%), the value for US being based on 2008 data. Hong-Kong ranked at the fourth position with a share of 8.1%. Japan, which remained until 2007 the fourth biggest exporter of high-tech goods, fell to the sixth position with a share of 6.2%. Two other countries: Singapore and South Korea recorded also significant shares of 6.2% and placed themselves at the level of Japan. The high performance of Hong-Kong and Singapore, both being relatively small Asian countries was driven by the important number of transiting high-tech products. Those two countries owe their ranks to the hub effect and re-exports of goods. 'Other Asian countries', Malaysia, Switzerland and Mexico registered their shares in exports of high-tech products ranging from 5.3% to 2.4%. Close behind came Thailand, Canada and Philippines with shares between 1.8% and 1.1%. The remaining main EU partners, Israel, India, Norway, Russian Federation, Indonesia, Brazil and Australia each recorded global export shares in high-tech products below 1%.

In 2009, the 21 largest exporting countries (entities) accounted for 98.6% of global exports in high-tech products.

High-tech employment at regional level

Figure 2 shows the regional discrepancies in high-tech sectors (by [NACE Rev. 2](#)) as a share of total employment. This figure combine the national average for each country as well as the regions with the lowest and highest shares of employment in high-tech sectors. At EU-27 level, the high-tech sectors (high-tech manufacturing and high-tech KIS) represented 3.7% of total employment in EU-27 in 2010 with two-thirds of persons occupied in high-tech knowledge-intensive services one-third occupied in high-tech manufacturing.

The national and regional highest and lowest shares vary significantly from country to another and some significant discrepancies can be observed at the regional level in the countries.

With regards to national averages, 18 out of 32 observed countries registered values higher than the EU-27 average (3.7%) with the rates of more than 5.0% in Ireland, Finland, Switzerland, Denmark, Malta, Slovenia and Hungary. On the other hand, the lowest national shares of high-tech sectors in total employment below 2.5% were registered in Portugal, Greece, Cyprus, Lithuania, Romania and Turkey. It must be noted that 6 European countries (Estonia, Cyprus, Latvia, Lithuania, Luxembourg and Malta) and Iceland are classified only at country level, taking into account the regional data presented in Figure 2.

At regional level, especially capital regions or those situated close to capitals, high shares of employment in high-tech sectors are often observed. Berkshire, Buckinghamshire and Oxfordshire (United Kingdom), situated in close proximity to London, stood out with 9.7% of their labour force in high-tech sectors. The following regions rated similarly: Hovedstaden (DK) with 9.5%, Province Brabant Wallon (BE) with 8.9%, Stockholm (SE) with 8.7% and Praha (CZ) with 8.0%. By contrast, the lowest shares of less than 1% were registered in Samsun (TR), region Nord-Est (RO), Dytiki Ellada (EL), and Región de Murcia (ES). Spain, Romania, Turkey, France, the United Kingdom and Poland, showed the biggest regional discrepancies when assessed by the ratio of the highest share to the lowest share. The lowest discrepancies in employment between regions were observed in Ireland, Switzerland, Slovenia, the Netherlands and Slovakia.

Data sources and availability

High-tech statistics uses various other domains and sources mainly within Eurostat's official statistics ([CIS](#) , [COMEXT](#) , [HRST](#) , [LFS](#) , [SBS](#) , [SES](#) , PATSTAT and R & D). Its coverage and availability is therefore

dependent on these other primary sources.

The **sectoral approach** is an aggregation of manufacturing industries according to technological intensity (R & D expenditure/value added) and based on the [Statistical classification of economic activities in the European Community \(NACE\)](#) at 2- or 3-digit level for compiling aggregates related to high-technology, medium high-technology, medium low-technology and low-technology. Services are mainly aggregated into knowledge-intensive services (KIS) and less knowledge-intensive services (LKIS) based on the share of tertiary educated persons at NACE 2-digit level.

Note that due to the revision of the NACE from NACE Rev. 1.1 to NACE Rev. 2 the definition of high-technology industries and knowledge-intensive services changed. For high-tech statistics it means that two different definitions (one according NACE Rev. 1.1 and one according NACE Rev. 2) are used in parallel and the data according to both NACE versions are presented in separated tables depending on the data availability.

Within the sectoral approach, a second classification has been created - Knowledge Intensive Activities - based on the share of tertiary educated people in each sectors of industries and services according to NACE at 2-digit level and for all EU 27 Member States. A threshold was then applied to rank sectors as knowledge intensive. In contrast to first sectoral approach mixing two methodologies one for manufacturing industries and one for services, the KIA classification is based on one methodology for all the sectors of industries and services.

The aggregations in use are total Knowledge Intensive Activities (KIA) and Knowledge Intensive Activities in Business Industries (KIABI). Two versions are in use also for Knowledge Intensive Activities one according NACE Rev. 1.1 and one according NACE Rev. 2. The data in this article are according NACE Rev. 2.

The **product approach** was devised to complement the sectoral approach. The product list is based on the calculations of R & D intensity by groups of products (R & D expenditure/total sales). The groups classified as high-technology products are aggregated on the basis of the [Standard international trade classification \(SITC\)](#) . The product approach is used for data on high-tech trade.

Due to the revision of SITC from SITC Rev. 3 to SITC Rev. 4 the definition of high-tech products has also changed. The data in this article are according SITC Rev. 4.

High-tech patents and biotechnology patents are defined according to the **patent approach** . The groups are aggregated on the basis of the [International patent classification \(IPC\)](#) - 8th edition. Biotechnology patents are also aggregated on the basis of the IPC - 8th edition.

For more detailed information of the various high-tech definitions see:

Context

Europe 2020

Investment in research, development, education and skills is one of the European Union's central policy areas. These key areas are essential to economic growth and to the development of the knowledge-based economy. The Europe 2020 strategy sets out a vision of Europe's social market economy for the 21st century. It aims to turn the EU into a smart, sustainable and inclusive economy that delivers high levels of employment, productivity and social cohesion. Innovation is a motor for economic progress: it is therefore a key element of Europe 2020.

Europe 2020 puts forward three priorities that go together and reinforce each other:

- smart growth: developing an economy based on knowledge and innovation;
- sustainable growth: promoting a more resource efficient, greener and more competitive economy;
- inclusive growth: fostering a high-employment economy, delivering social and geographical cohesion.

Innovation Union

The European Commission has defined seven flagship initiatives to create progress under the Europe 2020 strategy. One of these is the "Innovation Union", supporting 'Smart growth'. The Innovation Union initiative improves the framework for research and innovation in the EU. It also improves the access to finance. The aim is to ensure that innovative ideas can be turned into products and services that create growth and jobs.

A key element of the Innovation Union is to complete the [European Research Area \(ERA\)](#) . ERA aims to increase the competitiveness of European research institutions by bringing them together and encouraging a more inclusive way of work. Increased mobility of knowledge workers and deeper co-operation among EU research institutions are central goals of ERA.

ERA should inspire the best talents to enter research careers in Europe and stimulate industry to invest more in European research. It enables European researchers to develop strong links with partners around the world, so that Europe benefits from the progress of knowledge worldwide, contributes to global development and takes a leading role in international initiatives to solve global issues.

However, there are still national and institutional barriers which limit the development of ERA. In 2008, the European Commission and the Member States launched new initiatives to develop ERA, including the 'Ljubljana Process' to improve the political governance of ERA. Several initiatives on specific areas have been initiated. These initiatives aim at establishing partnerships with Member States and business, universities and research organizations to develop the ERA in their specific field.

One of these five new initiatives intends to create a [European Partnership for Researchers for mobility and career development](#) . Improving the mobility of researchers will improve the flow of knowledge throughout Europe, balance demand and supply for researchers at the European level, help create centres of excellence and improve the skills of researchers in Europe. Improving career prospects for researchers in Europe will stimulate more young people to choose a research career, help keep researchers in Europe and attract more talented non-European researchers.

Table 4: Motivation to introduce environmental innovations — proportion of innovative enterprises reporting specified motivations, 2008(% of innovative enterprises) - Source: Eurostat (inn_cis6_ecomot)

Europe has a long-standing tradition of producing inventions. However, commentators often focus on an entrepreneurial gap in order to explain why some ideas for new products or services do not become a success in the marketplace, or why other ideas relating to new processes do not get implemented, thereby surrendering the opportunity to make efficiency gains in production or within organisations.

This article looks at the state of [innovation](#) in the [European Union \(EU\)](#) by presenting data on where innovation takes place and how many [enterprises](#) engage in innovation and what proportion of their turnover comes from new or significantly improved products, as well as the environmental benefits of innovation (including reductions in the use of energy).

Main statistical findings

Extent of innovation

Among the EU Member States the highest propensity to innovate in 2008 (see Figure 1) was recorded in Germany (79.9% of all enterprises), followed by Luxembourg (64.7%) – these were the only Member States where more than 60% of enterprises were innovative – the [EU-27](#) average (excluding Greece) was 51.6%. The lowest propensities to innovate were recorded in Latvia (24.3%), Poland (27.9%) and Hungary (28.9%) – the only Member States where the proportion of innovative enterprises was below 30%. Estonia, Cyprus and the Czech Republic were the only Member States that joined the EU in 2004 to report a propensity to innovate above the EU average. Note that [large enterprises](#) tend to innovate more than [small and medium-sized enterprises \(SMEs\)](#) and, as such, these figures for the EU Member States may, at least to some degree, reflect the enterprise structure of each domestic economy.

New or significantly improved products contributed a relatively small proportion of total turnover among innovative enterprises in 2008, with 15 of the 25 Member States for which data are available reporting single-digit shares (see Figure 2). These products did however account for a higher proportion of sales in Malta (24.7%), Bulgaria (17.0%), Hungary (16.6%), the Czech Republic (16.1%) and Slovakia (14.9%).

Large enterprises (with 250 or more employees) were more likely to have brought product innovations to market in 2008 than either [medium-sized enterprises](#) (50 to 249 employees) or [small enterprises](#) (10 to 49 employees); this pattern held for all of the Member States for which data are available – as shown in Table 1. Lithuania was the only Member State where the proportion of small enterprises with product innovations was above the average for all enterprises.

A similar size class breakdown for process innovations that are developed within the enterprise also showed

that large innovative enterprises were generally more likely to introduce such innovations: the main exception to this was Cyprus where process innovations were much less likely to have been introduced in large enterprises than in small or medium-sized enterprises, while this was also true, to a lesser extent, in Bulgaria and Lithuania; in Romania, Poland, Portugal and Finland small enterprises were more likely than large enterprises to have introduced process innovations, while in Italy and Slovenia medium-sized enterprises were the most likely to have introduced process innovations.

Innovations with environmental benefits

The environmental benefits of an innovation can occur during the production of a good or service, or during the after sales use of a good or service by the end-user. Table 2 shows the proportion of innovative enterprises having introduced environmental benefits with a distinction between benefits from the production or from the use of the innovative product: six different benefits related to production are presented as well as three benefits related to use. Among the benefits from production, the most common benefits were generally a reduction in energy use or increased recycling. The main exceptions were: Estonia and Lithuania, where the most common benefit was reduced material use; Latvia, Austria and Poland (and Croatia), where the most common benefit was reduced pollution; and the Netherlands, where the most common benefit was the use of less polluting or hazardous materials. Among the benefits from after sales use, the most common benefit was reduced energy use; reduced pollution was a more common benefit in Cyprus, Latvia and Poland (as well as Croatia), whereas improved end of product life recycling was the most common benefit in Ireland and Portugal.

Table 3 focuses on innovations with reduced energy use and presents an analysis by innovator size class. In every Member State for which data are available, large enterprises were more likely than either small or medium-sized enterprises to have introduced innovations with reduced energy use during production. A similar situation can be seen for innovations which lead to reduced energy use by end-users, although there were exceptions; in Latvia such innovations were more common among small enterprises and in Lithuania they were more common among medium-sized enterprises.

The motivation for environmental innovations is presented in Table 4. The most common reason for introducing environmental innovations appears to be either because of existing environmental regulations or taxes on pollution or because of voluntary codes or agreements for environmental good practice. Current or expected market demand from customers was, however, the most common motivation in the Netherlands and Finland. Expected future environmental regulations or taxes were also often cited as a motivation, for example, in Malta. In every Member State, the availability of government financial incentives for environmental innovation was the least common motivation of the five reasons that were surveyed.

Data sources and availability

The [Community innovation survey \(CIS\)](#) collects information about product and process innovation, as well as organisational and marketing innovations. The legal basis for the collection of these statistics is [Regulation 1450/2004](#) of 13 August 2004 implementing [Decision 1608/2003/EC](#) concerning the production and development of Community statistics on innovation.

Innovations are based on the results of new technological developments, new combinations of existing technology, or the use of other knowledge acquired (by the enterprise). For the purpose of the CIS an innovation is defined as a new or significantly improved product (good or service) introduced to the market, or the introduction within an enterprise of a new or significantly improved process, as well as organisational and marketing innovations, including new logistics or distribution methods. Such innovations may be developed by the innovating enterprise or by another enterprise. However, purely selling innovations wholly produced and developed by other enterprises is not included as an innovative activity, nor is introducing products with purely aesthetic changes. Innovations should therefore be new to the enterprise concerned: for product innovations they do not necessarily have to be new to the market, and for process innovations the enterprise does not necessarily have to be the first one to have introduced the process.

Enterprises with innovation activity include all types of innovator, namely product and process innovators, as well as enterprises with only on-going and/or abandoned innovation activities. Enterprises may cooperate with other parties (for example, suppliers, competitors, customers, educational/research establishments) when

engaging in an innovative activity. The proportion of enterprises with innovation activity is also referred to as the propensity to innovate.

An environmental innovation is an innovation that creates environmental benefits compared with alternatives. The environmental benefits can be the primary objective or motivation of the innovation or the result of other innovation objectives.

Context

While Europe has a tradition of producing initial ideas (inventions), it is regarded by some as not being so good at bringing them to market; as such, EU policy in this field increasingly aims to provide more focus to industry-driven, applied [research and development \(R&D\)](#) .

Education is another area seen as key to developing an innovation-oriented society, through the acquisition of entrepreneurial, managerial, scientific, mathematical and foreign-language skills, as well as digital literacy. Policymakers express concern at the numbers of science and technology graduates who directly apply their education once they move into the [labour market](#) , while a lack of job mobility between universities and business may potentially hinder the transfer of ideas, thereby reducing the EU's innovation performance (see [R&D personnel](#)).

In October 2006, the [European Parliament](#) and the [Council](#) adopted a [Decision 1639/2006/EC](#) establishing a competitiveness and innovation framework programme (CIP) for the period 2007-2013. With SMEs as its main target, the competitiveness and innovation framework programme aims to support innovation activities (including eco-innovation), provide better access to finance and deliver business support services in the regions. It encourages the take-up and use of information and communication technologies and aims to help to develop the information society. Furthermore, it also promotes the increased use of renewable energies and energy efficiency. [Horizon 2020](#) is the title for the framework programme for research and innovation from 2013 through to 2020 – see the article on [science and technology introduced](#) for more information.

The [European Institute of Innovation and Technology](#) was established in March 2008 to increase sustainable growth and competitiveness by reinforcing the innovation capacity and, most importantly, the innovation impact of the EU. Its aim is to bring together higher education, research and innovation through the creation of 'knowledge and innovation communities'.

In September 2009, the European Commission adopted a Communication titled ' [reviewing Community innovation policy in a changing world](#) ' (COM(2009) 442 final). In October 2010, as one of the seven flagship initiatives of the [Europe 2020 strategy for smart, sustainable and inclusive growth](#) , the European Commission adopted a Communication on an ' [Innovation Union](#) ' (COM(2010) 546 final). This sets out a comprehensive innovation strategy for Europe, focusing on major areas of concern for citizens such as climate change, energy efficiency and healthy living. It pursues a broad concept of innovation, not only technological, but also in business models, design, branding and services that add value for users. It includes public sector and social innovation as well as commercial innovation. It aims to involve all actors and all regions in the innovation cycle. The policies in the innovation union aim to do three things:

- make Europe into a world-class science performer;
- revolutionise the way public and private sectors work together, notably through innovation partnerships;
- remove bottlenecks like expensive patenting, market fragmentation, slow standard setting and skills shortages that currently prevent ideas getting quickly to market.

The [European innovation scoreboard](#) , formerly used for assessing the innovation performance of EU Member States, has been reworked to improve international comparability and to include a number of research-oriented indicators in line with the purpose of monitoring the implementation of the innovation union.

European innovation partnerships (EIPs) also form part of the innovation union and are designed to act as a framework to address major societal challenges, bringing together activities and policies from basic research through to market-oriented solutions. The first EIP announced in February 2011 is a [partnership for active and](#)

[healthy ageing](#) and has three main objectives, namely to:

- enable EU citizens to lead healthy, active and independent lives while ageing;
- improve the sustainability and efficiency of social and healthcare systems;
- boost the competitiveness and markets for innovative products and services that respond to the ageing challenge.

The partnership for active and healthy ageing is focused on prevention and health promotion, integrated care, and independent living for older persons. Its overarching target is to increase the average number of healthy life years within the EU-27 population by two years by 2020.

Figure 3: EU patent citations(EPO), 1997-2007(number) - Source: Eurostat (pat_ep_cti)

This article provides information on [patent applications](#) in the [European Union \(EU\)](#) . [Intellectual property rights](#) , in particular [patents](#) , provide a link between [innovation](#) , [inventions](#) and the marketplace. Applying for a patent makes an invention public, but at the same time gives it protection; from a consumers perspective it may be argued that patent protection motivates the invention of new goods and services but at the same time may slow down the diffusion of new technologies, techniques and products. A count of patents is one measure of a country's inventive activity and also shows its capacity to exploit knowledge and translate it into potential economic gains. In this context, indicators based on patent statistics are widely used to assess the inventive and innovative performance of a country.

Main statistical findings

From a low point of 51375 [EU-27](#) patent applications filed with the [European Patent Office \(EPO\)](#) in 2002, there was a steady increase during four years. Having peaked at 57424 applications in 2006, the number of EU-27 patent applications to the EPO fell for four consecutive years, although latest estimates show that patent applications (54415) in 2010 remained higher than at the start of the decade. During the period 2002 to 2006, the number of EU-27 patent applications to the EPO increased, on average, by 2.8% per annum, while during the period 2006 to 2010 the reduction in the number of patents was, on average, 1.3% per annum. Over the whole of the last decade (2000 to 2010), the number of EU-27 patent applications filed with the EPO increased by 2704 – see Figure 1.

Among the EU Member States, Germany had by far the highest number of patent applications to the EPO, some 21724 in 2010 (39.9% of the EU-27 total). In relative terms, Sweden reported the highest number of patent applications per million inhabitants (306.7), followed by Germany (265.6), Denmark (241.7) and Finland (217.7). Between 2005 and 2010 the number of patent applications filed with the EPO fell in 12 of the EU Member States, the largest contractions being recorded in Germany, the United Kingdom, Italy and the Netherlands. The downturn in the number of patent applications in these countries more than outweighed the

increases recorded in the remaining 17 Member States, where the highest absolute gains in numbers of applications were recorded in Sweden, France and Poland. Note that the information for Japan and the United States is only available through to 2008 and that, as such, the large reduction in patent applications to the EPO for these two countries may, to some degree, reflect the onset of the financial and economic crisis (see Table 1).

EU-27 high-technology patent applications to the EPO represented 23.7% of all patent applications in 2001. Their relative importance declined after this, as did their absolute number – from 12188 in 2001, there was a relatively steady reduction through to 2008 (despite growth in 2004). This was followed by a collapse in the number of high-technology applications in 2009, with the total falling to 4765 (provisional data). This considerable and continued reduction in high-technology patent applications filed with the EPO may reflect the length of patent procedures.

A relatively small group of EU Member States had a far higher propensity to make high-technology patent applications to the EPO. The highest rates (per million inhabitants) were recorded in Sweden, Finland, Germany, the Netherlands, Belgium and France (all between 22.2 applications per million inhabitants and 17.7 applications per million inhabitants), while Denmark, and Austria were the only other EU Member States to record double-digit ratios.

Just under two fifths (39.3%) of EU-27 patent applications to the EPO in 2009 were from single inventors, while the remainder were co-patents (see Figure 2). By far the most common type of co-patent involved multiple inventors/applicants from a single country – in fact, such co-patents made up an overall majority (53.1%) of all patent applications. Patent applications involving inventors from more than one country made up the remaining 7.6% of patent applications to the EPO.

Citations are the references in search reports used to assess an invention's patentability; they document the state of the art at the time of the claimed invention. Citations in a patent application may be references to other patents or to other relevant reference material, such as scientific journals. Figure 3 shows that EU patent citations were more likely to refer to EU patent publications than to non-EU patent publications; this is an established pattern that could be observed each year between 1997 and 2007. The number of patent citations in more recent years is lower than in previous periods, reflecting the practice of citing older patents.

Data sources and availability

Since 2007, Eurostat's production of European Patent Office (EPO) data has been based almost exclusively on the EPO's worldwide statistical patent database (PATSTAT). The EPO grants European patents for the contracting states to the [European Patent Convention \(or Munich Convention\)](#), of which there are currently 38 – the EU Member States, the [EFTA Member States](#), several other candidate countries (Croatia, the former Yugoslav Republic of Macedonia, Serbia and Turkey), as well as Albania, Monaco and San Marino.

European patent applications refer to applications filed directly under the EPC or to applications filed under the [Patent Cooperation Treaty \(PCT\)](#) and designated to the EPO ([Euro-PCT](#)). Patent applications are counted according to the year in which they are filed and are assigned to a country according to the inventor's place of residence, using fractional counting if there are multiple inventors.

By contrast, the United States Patent and Trademark Office (USPTO) data refer to patents granted; data are recorded by year of publication as opposed to the year of filing. This methodological difference implies that any comparison between EPO and USPTO patent data should be interpreted with caution.

High-technology patents are counted following criteria established by the trilateral statistical report (drafted by the EPO, USPTO and the Japan Patent Office (JPO)), where the following technical fields are defined as high-technology groups in accordance with the international patent classification (IPC): computer and automated business equipment; micro-organism and genetic engineering; aviation; communication technology; semiconductors; and lasers.

Context

Intellectual property law establishes protection over intangibles – for example, when a manufactured product is sold, the product itself becomes the property of the purchaser, however, intellectual property rights allow intangible elements to remain in the ownership of the creator; these intangibles include (among others) the idea itself, or the name or sign/logo used to distinguish the product from others.

Patents and trademarks are common ways to protect industrial property. Patents are a limited term exclusive right granted to an inventor, maintained through the payment of fees. While patents are generally used to protect research and development ([R&D](#)) results, they are also a source of technical information, which can potentially prevent re-inventing and re-developing ideas. A count of patents shows a country's capacity to exploit knowledge and translate it into potential economic gains; in this context, patent statistics are widely used to assess the inventive and innovative performance of countries. Most studies show that innovative enterprises tend to make more use of intellectual property protection than enterprises that do not innovate. Enterprise size and the economic sector in which an enterprise operates are also likely to play an important role in determining whether an enterprise chooses to protect its intellectual property; for this reason the structure and specialisation of an economy plays a part in the level of patent applications.

The use of patents is relatively restricted within the EU – this may be due to a range of influences: their relative cost; the overlap between national and European procedures; or the need for translation into foreign languages. Furthermore, the increasing number and complexity of patent applications worldwide has resulted in a backlog of pending applications, while the constant expansion of the human knowledge base makes it increasingly difficult for patent offices to keep abreast of technological developments.

The [European Council](#) held in Lisbon in March 2000 called for the creation of a Community patent system to address shortcomings in the legal protection of inventions, while providing an incentive for investments in R&D. In July of the same year, the [European Commission](#) made a first proposal for the creation of a Community patent: this was discussed at various levels and despite a number of proposals and amendments for a Council Regulation during 2003 and 2004 no legal basis was forthcoming. In April 2007, the European Commission released a Communication titled ' [Enhancing the patent system in Europe](#) ' (COM(2007) 165 final), stating that European patent systems were more expensive, uncertain and unattractive than those in non-member countries.

In July 2008, the European Commission adopted a Communication titled ' [An industrial property rights strategy for Europe](#) ' (COM(2008) 465 final) foreseeing the development of legislation and proposing that the harmonisation of patent law should make it easier for European enterprises to patent their inventions both within and outside the EU.

On 4 December 2009, the European Council unanimously adopted conclusions on an enhanced patent system in the EU. The package agreed covers two main areas: firstly, agreement on the approach to be adopted in order to move towards an EU patent regulation; secondly, an agreement on establishing a new patent court in the EU. It is anticipated that these measures will together make it less costly for businesses to protect innovative technology and make litigation more accessible and predictable. However, the creation of the EU patent depends on a solution being found for translation arrangements which were the subject of European Commission proposal in July 2010 for a ' [Council Regulation on the translation arrangements for the European Union patent](#) ' (COM(2010) 350 final). In December 2010, it became clear that there was not unanimous agreement on this proposal: in February 2011 the [European Parliament](#) gave its consent for the use of the [enhanced cooperation](#) procedure to make progress on this issue and this was authorised by the Competitiveness Council in March 2011 (with the participation of 25 EU Member States). In April 2011, the European Commission adopted proposals for ' [Implementing enhanced cooperation in the area of the creation of unitary patent protection](#) ' (COM(2011) 215 final).

Patent statistics backgrounds

[Intellectual property rights](#) and in particular [patents](#) provide a link between [innovation](#) , [inventions](#) and the marketplace. Applying for a patent makes an invention public, but at the same time gives it protection. A count of patents is one measure of a country's inventive activity and also shows its capacity to exploit knowledge and translate it into potential economic gains.

In this context, indicators based on patent statistics are widely used to assess the inventive and innovative performance of a country. This article sketches the context and methodology of statistics on [patent applications](#) and grants in the [European Union \(EU\)](#) and some other European countries.

An analysis of the most recent EU data can be found in the Statistics explained dedicated to [patent statistics](#) .

Data sources and availability

From 2007 onwards, Eurostat 's production of [European Patent Office \(EPO\)](#) and [United States Patent and Trademark Office \(USPTO\)](#) data has been based on the [EPO Worldwide statistical patent database](#) . This was developed by the EPO in 2005, using their collection and knowledge of patent data.

European patent applications refer to applications filed directly under the European Patent Convention or to applications filed under the Patent Co-operation Treaty (PCT) and designated to the EPO (Euro-PCT), regardless of whether the patents are granted or not. For patent applications to the EPO all direct applications (EPO-direct) are taken into account, but among the PCT applications (applications following the procedure laid down by the PCT) made to the EPO, only those that have entered into the regional phase are counted. Patent applications are counted according to the priority date (the year in which they were filed anywhere in the world) at the EPO and are broken down according to the [International patent classification \(IPC\)](#) . Applications are assigned to a country according to the inventor's place of residence, using fractional counting if there are multiple inventors to avoid double counting. To normalise the data, the total number of applications at the EPO is divided by the national population and expressed in terms of patent applications per million inhabitants.

A patent application to the EPO can be valid in several countries and at most in all of the Contracting States of the European Patent Convention. In July 2009, the Convention was in force in 36 countries (all [EU Member States](#) plus Switzerland, Iceland, Liechtenstein, Norway, Monaco, San Marino, Croatia, the former Yugoslav Republic of Macedonia and Turkey). In addition to the Contracting States, three other countries (Albania, Serbia and Bosnia and Herzegovina) have concluded an 'extension agreement' with the EPO, by which these states can also be designated in a European patent application.

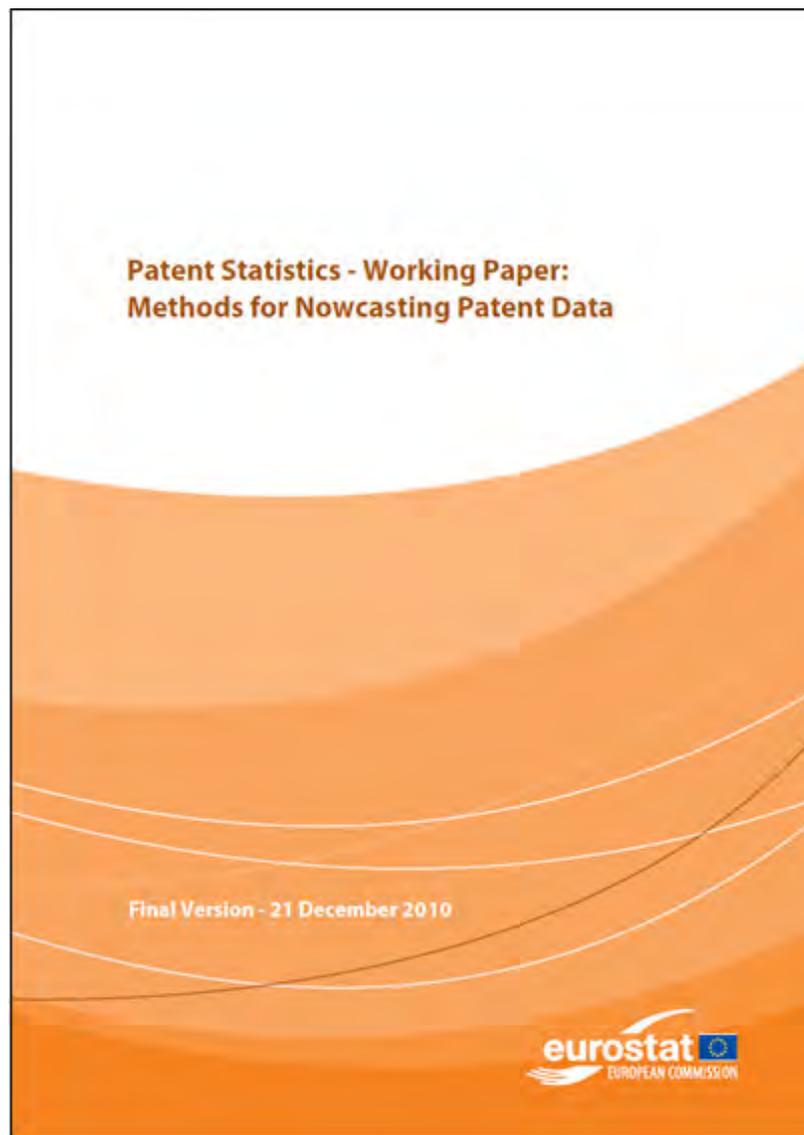

The falling trend in patent applications in the last years is linked to the length of patenting procedures and should not be interpreted as a real decline in patenting activity. For this reason the 2009 figures in Eurostat's reference database are flagged as provisional or as estimates.

Patent indicators provide a measure of the innovative performance at country, firm or region level. Nevertheless, indicators are criticized as being "outdated". This is due to the fact that information on patent applications is disclosed to the public 18 months or more after priority date. This issue is known as "timeliness". In order to overcome this, Eurostat carried out a study where nowcasting methods have been discussed and developed.

The main purpose of this study it was to do the presentation of the existing methods for nowcasting of patent data to the European Patent Office (EPO) and the proposal of improved methods. An evaluation of these methods has been performed and conclusions regarding the most adequate methods for most of the countries have been drawn.

Moreover, an attempt to apply econometric models for nowcasting patent applications to the EPO was attempted as well as a comparison analysis. The existing econometric models are presented and 6 new models are detailed. A comparison analysis is performed and the strengths and weaknesses of each model is outlined.

In contrast to EPO data, the USPTO data refers to patents granted. Patents are allocated to the country of the inventor, using fractional counting in the case of multiple inventor countries. Comparisons between EPO and USPTO patents data should be interpreted with caution.

Patent statistics - Working Paper: Methods for Nowcasting patent data

Patent Statistics at Eurostat: Methods for Regionalisation, Sector Allocation and Name Harmonisation

Patent Statistics: Eurostat quarterly review of the literature on patent statistics

What is new?

KUL / Eurostat

Patent Statistics at Eurostat: Methods for Regionalisation, Sector Allocation and Name Harmonisation

Over the last decade, Eurostat regularly increased and improved the dissemination of patent data with the production of new indicators on economic activities. The core of the work is linked to the [European Research Area \(ERA\)](#) , and to the priorities of the [Europe 2020 strategy](#) . There is therefore a need to enhance the information available in patent databases.

In that context Eurostat, in collaboration with the Katholieke Universiteit Leuven (K.U. Leuven), developed and implemented several innovative methodologies to be applied on PATSTAT data. They relate to regionalisation of patentee and inventors addresses (according to the [NUTS](#) classification), as well as sector allocation and name harmonisation of applicants.

This compendium of methodologies developed by Eurostat in the field of patent statistics contributes to the further development of indicators that are instrumental for analysis and policy development. It presents several methodological enhancements to deal with limitations in patent data sources. First, until now, no exhaustive

sector allocation was available for identifying the nature of the applicant: individual, firm, university, public research organisation... Eurostat has bridged this gap by developing an exhaustive sector allocation methodology that is now made available for research and policy analysis.

Second, regarding applicant names in existing patent data sources, non-uniformity is the rule rather than the exception. Therefore, name harmonisation algorithms have been developed with a considerable impact in terms of coverage, resulting in highly improved indicator accuracy. Third, regionalization methodologies have been developed to better capture the regional dimension of technology development within the European Research Area (at EU-27 level).

These enhancements allow greater efficiency and accuracy in patent indicator extractions at regional, sectoral and institutional level, and are hence a considerable step forward in monitoring innovation systems in terms of technological activities.

Regionalisation of patent data

Until recently, economic geography has played only a minor role in economic theory, despite the obvious fact that economic activities are not equally distributed over space. Relatively little empirical attention has been paid to the emergence and growth of regional clusters of technological activities. The existing evidence is mostly based on case study research, while large-scale empirical evidence or verification is rather scarce.¹⁶⁸ One reason for this lack of large-scale empirical evidence on the phenomenon of technology clusters is the low availability of quantitative data at the region-technology level, covering regions worldwide over longer periods. Patent data, which provide information on the date and geographic location of technological development and on the organisations and institutions involved, have become increasingly available at regional level. However, in order to be able to construct patent indicators from them, addresses of inventors and patentees need to be allocated to regions. This section outlines a methodology for achieving this.

Regional patent statistics build on the allocation of inventor and patentee addresses to regions. This allocation or regionalisation exercise requires first of all an exhaustive list of postcodes and city names and their respective regions. Within Europe, the NUTS classification is a hierarchical system used to divide the economic territory of the EU4. It is used in the collection, development and harmonisation of EU regional statistics; in socio-economic analyses of the regions; and in the framing of EU regional policies.

Sector allocation

A corollary of this conception of innovation dynamics is the need for refinements in patent indicators. Sector assignment — i.e. identifying whether patentees are companies (private business enterprise), universities and higher education institutions, or governmental agencies — becomes a necessary condition for further analysis of the dynamics underlying technological performance.

This section outlines an updated version of the sector allocation methodology that was developed in 2006.¹⁶⁹ It starts with an overview of previous efforts in sector assignment of patentees, indicating the relevance of additional development efforts. After that, the currently developed methodology and its outcomes are outlined. Conclusions are drawn on the performance of the current sector allocation methodology, and future avenues for further improvement are delineated.

Name harmonisation

The development of patent indicators on the micro-level of specific entities like companies, universities and individual inventors is faced with specific concerns stemming from the heterogeneity of patentee names that appear in patent documents within and across patent systems. Whereas this poses no challenge to the functioning of the patent system itself, it does complicate analyses at patentee level: the analyst is confronted with inconsistencies such as spelling mistakes, typographical errors and name variants, which often also reflect idiosyncrasies in the organisation of R&D and/or IPR activities within a single organisation.

With the objective of reconciling completeness and accuracy, a comprehensive methodology was developed to obtain harmonised patentee names in an automated way. The methodology consists of several harmonisation layers. In a first layer, which emphasised accuracy or precision', the number of unique patentee names was

¹⁶⁸Lecocq, 2013

¹⁶⁹Van Looy, du Plessis & Magerman, 2006

reduced by approximately 20% and the average number of patents per patentee increased from 5.5 before to 6.8 after harmonisation. In a second layer, emphasis was placed on recall'(a high coverage in terms of patent volumes). This layer covers the top 500 most active patentees, as well as university patentees. For the top 500 patentees, this additional harmonisation layer resulted in allocating over 30000 patentee names to the top organisations, raising their aggregated patent volume by almost 70%.

Method for harmonizing applicants' names and PATSTAT harmonized PERSON table

The K.U.Leuven/Eurostat method for harmonized patent applicant's names is a comprehensive method to achieve harmonization of patentee names in an automated way. This method was applied on all applicant names in the PERSON table of EPO's Worldwide Patent Statistical Database (PATSTAT), edition April 2009, resulting in a new PERSON table with harmonized applicant names. The developed method is based on the contents of the name and country address of the applicant name, no other information is used in the harmonization process. All names are processed by a step-wise validation process based on rules: character cleaning; punctuation cleaning; legal from indication treatment; common company word removal; spelling variation harmonization; condensing; umlaut harmonization. About 4 000 search and replace rules are executed for every step to handle the particular issue.

See: '[Data production methods for harmonized patent statistics: Patentee name harmonization](#)'

A first version of the method was applied on EPO and USPTO applicant names in 2006.¹⁷⁰

An extended methodological outline describing more in details all aspects of: The Name harmonization versus legal entity harmonization and consolidation; the Automated rule-based system; the Trade-off between precision/accuracy and recall/completeness and the possibilities for Extending the method and for applying it on the EPO's Worldwide Patent Statistical Database can be found under the following link: '[Harmonizing harmonized patentee names: an exploratory assessment of top patentees](#)'

Data production methods for harmonized patent statistics: Patentee sector allocation

In addition to the 'Method for harmonizing applicant's names' the K.U. Leuven and Eurostat published in 2006 also a working paper on a method for sector allocation.¹⁷¹This method on assignee sector allocation has been reviewed and improved recently. The latest results are available in the working document '[Evolution of innovation actors and the influence of legislation](#)' .

In applying numerous rules based on keywords and/or clues patent applications are classified to five different institutional sectors:

- individual applicant;
- firms or business enterprise;
- government (agencies) and (private or public) [non-profit organizations](#) ;
- university/higher education;
- [hospitals](#) .

More than 85% of all patent applications to the EPO are made by the business enterprises sector. For around 9% of the patent applications individual applicants can be identified. Whereas the patenting activity of the hospital sector is very small the patent applications of the remaining two sectors make up respectively about 2%. However one should bear in mind that these percentages are calculated for all patent applications to the EPO. This implies that the results may vary significantly across countries.

The working document focuses on the higher education sector and studies the role of legislation on the patenting activity in this sector.

¹⁷¹Van Looy, B., du Plessis, M. & Magerman, T. (2006) Data Production Methods for Harmonized Patent Indicators: Assignee sector allocation. Eurostat Working Paper and Studies, Luxembourg.

The full methodology is described in the recent Eurostat working document '[Data production methods for harmonized patent statistics: Patentee sector allocation \(2009\)](#)' .

Eurostat quarterly review of literature on Patent Statistics - June 2012

This report has been prepared in the framework of Eurostat's work on patent statistics. It consists of an extensive targeted review of the existing and currently developed methodological, analytical and scientific material and of the most recent relevant literature in the following domains:

- PATSTAT data quality
- Name harmonisation and gender;
- Existing information and databases at institutional or company level or business surveys: comparison and possible integration and matching of data for analytical purposes;
- Development of methods on patent data based on technical fields: biotechnology, nanotechnology, environmental technologies, energy, measurement of climate change, eco-innovation, technological innovation, other emerging fields;
- Development of methods for compiling information on patent families and citations;
- Regionalisation.

The report essentially consists of a collection of electronic articles, working papers and other publications available free of charge. An update of the report will be made available every three months.

Flyer: Conference on Patent statistics for Decision Makers 2012

Conferences on Patent statistics

A conference on **Patent Statistics for Decision Makers - Knowledge Assets and Economic Growth** , will take place in Paris, on 28th and 29th November 2012. The event is organised by the Organisation for Economic Co-operation and Development (OECD) and the European Patent Office (EPO) in co-operation with Eurostat , Japan Patent Office (JPO) , Korean Intellectual Property Office (KIPO) , National Science Foundation (NSF) , United States Patent and Trademark Office (USPTO) and World Intellectual Property Organization (WIPO) .

The goal of the Patent Statistics for Decision Makers 2012 conference is to present the latest empirical evidence relying on patent statistics and to discuss findings with decision makers from both the private and the public sector. The conference aims to share frontier knowledge on topics relevant to policy-makers, academics, companies, and practitioners including:

- Patenting and the development of new technological fields (e.g. clean technologies, health technologies)
- Defining patent “quality” and assessing the economic and technical value of patents
- Patenting strategies, patent thickets, competition policy and standards
- The market for ideas: knowledge-based assets, knowledge markets, and the organisation of the firm

- Innovation-based entrepreneurship, and the role of IP for Small and Medium Enterprises (SMEs)
- The “IP bundle”: the use of patents and other IP as strategic assets
- Intellectual assets and economic growth
- Patenting trends and patent policies in emerging economies
- Patent system reforms: adapting IP rights to the changing economic landscape
- Patent fees, patenting costs, and the functioning of patent systems

The event is targeted at decision makers, academics, analysts, practitioners and other experts dealing with innovation, intangible assets, academic entrepreneurship, enterprise dynamics, and science and technology-related issues.

Context

Europe 2020

Investment in research, development, education and skills is one of the European Union’s central policy areas. These key areas are essential to economic growth and to the development of the knowledge-based economy. The Europe 2020 strategy sets out a vision of Europe’s social market economy for the 21st century. It aims to turn the EU into a smart, sustainable and inclusive economy that delivers high levels of employment, productivity and social cohesion. Innovation is a motor for economic progress: it is therefore a key element of Europe 2020. Europe 2020 puts forward three priorities that go together and reinforce each other:

- smart growth: developing an economy based on knowledge and innovation;
- sustainable growth: promoting a more resource efficient, greener and more competitive economy;
- inclusive growth: fostering a high-employment economy, delivering social and geographical cohesion.

Innovation Union

The [European Commission](#) has defined seven flagship initiatives to create progress under the Europe 2020 strategy. The [Innovation Union](#), which describes itself as “one of the seven flagship initiatives of the Europe 2020 strategy for a smart, sustainable and inclusive economy”, released a [progress report](#). The report states, as Innovation Union goals, making “Europe into a world-class science performer”, removing “obstacles to innovation – like expensive patenting, market fragmentation, slow standard-setting and skills shortages – which currently prevent ideas getting quickly to market” and revolutionizing “the way public and private sectors work together, notably through Innovation Partnerships between the European institutions, national and regional authorities and business.”

The report includes updates on 34 commitments made in conjunction with the Europe 2020 goals, here are just a few:

- Put in place national strategies to train enough researchers (2011)
- Ensure cross border operation of venture capital funds (2011)
- Deliver the EU Patent (2014)
- Speed-up and modernise standard-setting (early 2011)
- Promote open access; support smart research information services (no date)
- Facilitate collaborative research and knowledge transfer (no date)

The Innovation Union [Communication](#) outlining a medium term strategy for innovation in Europe includes an action aiming at improving the economic exploitation of Intellectual Property Rights (IPR). Action 22 is formulated as follows:

- 22. By the end of 2011, working closely with Member States and stakeholders, the Commission will make proposals to develop a European knowledge market for patents and licensing. This should build on Member State experience in trading platforms that match supply and demand, market places to enable financial investments in intangible assets, and other ideas for breathing new life into neglected intellectual property, such as patent pools and innovation brokering.

Patents are generally used to protect R&D results, but they are also significant as a source of technical information, which may prevent re-inventing and re-developing ideas because of a lack of information. However, the use of patents is relatively restricted within the EU. There are a number of possible reasons for this including:

- their relative cost;
- the overlap between national and European procedures;
- the need for translation into foreign languages.

Most studies in this area show that innovative enterprises tend to make more use of intellectual property protection than companies that do not innovate. Enterprise size and the economic sector in which an enterprise operates are also likely to play an important role in determining whether an enterprise chooses to protect its intellectual property.

The [European Council](#) held in Lisbon in March 2000 called for the creation of a Community patent system to address shortcomings in the legal protection of inventions, while providing an incentive for investments in R&D and contributing to the competitiveness of the economy as a whole. In July 2000 the European Commission made a first proposal for the creation of a Community patent. This was discussed at various levels and despite a number of proposals and amendments for a Council Regulation on the Community patent during 2003 and 2004 no legal basis was forthcoming. In April 2007 the European Commission released a [Communication Enhancing the patent system in Europe](#). This demonstrates that the European patent system is more expensive, uncertain and unattractive compared to patent systems in competitor states. The report also underlined the European Commission's belief that a more competitive and attractive Community patent system can be achieved, based upon the creation of a unified and specialised patent judiciary, with competence for litigation on European patents and future Community patents.

All these elements have been under examination under successive EU Council Presidencies and culminated with the adoption, on 4 December 2009, of Council conclusions on an "Enhanced patent system for Europe" ([17229/09](#)) and a general approach on a draft regulation on the EU patent ([16113/09 ADD1](#)). However, the translation arrangements for the EU patent remained out of the scope of these conclusions.

The Council conclusions were adopted without prejudice to the opinion requested on 25 June 2009 to the European Court of Justice on the compatibility of the envisaged system with EU law.

On 2 July 2010, the Commission submitted to the Council a proposal on the translation arrangements for the EU patent ([11805/10](#)).

After verifying, on 10 December 2010, the failure to reach the required unanimity on the translation arrangements in the foreseeable future, and therefore the impossibility to establish a unitary patent protection in the entire EU within a reasonable period, several member states expressed their wish to establish an enhanced cooperation in the area of the creation of unitary patent protection.

On 15 February 2011, the European Parliament gave its consent to proceed with the enhanced cooperation.

At its meeting on 10 March the Council authorized the launch of enhanced cooperation on the creation of a unitary patent title, in which 25 member states will participate. This is the first step towards a streamlined and less costly patenting system. This complex issue has been discussed for decades.

The enhanced cooperation will be open for those member states which are currently not participating (Italy and Spain) to join at any time, and businesses from those countries will have access to the unitary patent protection on the territory of the participating member states.

The EU came a step closer to getting a single patent system on December 2011, when a deal struck by European Parliament representatives and the Polish Presidency of the Council was backed by the Legal Affairs Committee. The new EU patent would be substantially cheaper and thus more competitive than current ones. Parliament succeeded in adapting the proposed regime to small firms' needs.

Before the new regulation can enter into force, it must be endorsed by the full Parliament, possibly at the February 2012 plenary session, and the Council.

The legislation is being dealt under the so-called "enhanced cooperation procedure", which allows groups of Member States to integrate policies further, even where others do not agree. Spain and Italy have so far opted out of work on the patent proposal, but could join the decision-making process at any time. This procedure was adopted to unblock the file, long stalled over language issues.

On January 2012, in the Statement of the members of the European Council - [Towards growth-friendly consolidation and job-friendly growth](#) (point 4 under Completing the Single Market) the participating Member States commit to reaching at the latest in June 2012 a final agreement on the last outstanding issue in the patent package.

The European Patent Office (EPO) is setting up an [Economic and Scientific Advisory Board](#) to address important patent-related economic and social issues in a more selective and dedicated way. Made up of internationally recognised experts with a global perspective and an emphasis on Europe, the board will advise the EPO on economic and social studies.

Using studies and analyses supplied by the EPO and external partners, the board will also provide early warnings on sensitive issues, and make policy recommendations.

Supported by the EPO's Chief Economist, the Advisory Board will be composed of representatives of companies, research establishments, universities and other institutions in Europe, Asia and the USA who are familiar with the patent system.

Notes

R & D budget statistics - transnationally coordinated research

Data from 2012, third round of experimental data collection.

This article presents the experimental results of the third round of data collection in the European Union (EU) and some EFTA and candidate countries on 'national public funding to transnationally coordinated research'. Transnational cooperation in research is one of the core elements of the European Research Area (ERA) and EU public policies to promote it have grown in importance.

National public funding to transnationally coordinated research is measured as the 'government budget appropriations or outlays for research and development (GBAORD)' directed towards three categories of research and development (R & D) performers and programmes: transnational public R & D performers located in Europe, Europe-wide transnational public R & D programmes and bilateral or multilateral public R & D programmes established between Member State governments or with EFTA and candidate countries (see Data sources and availability).

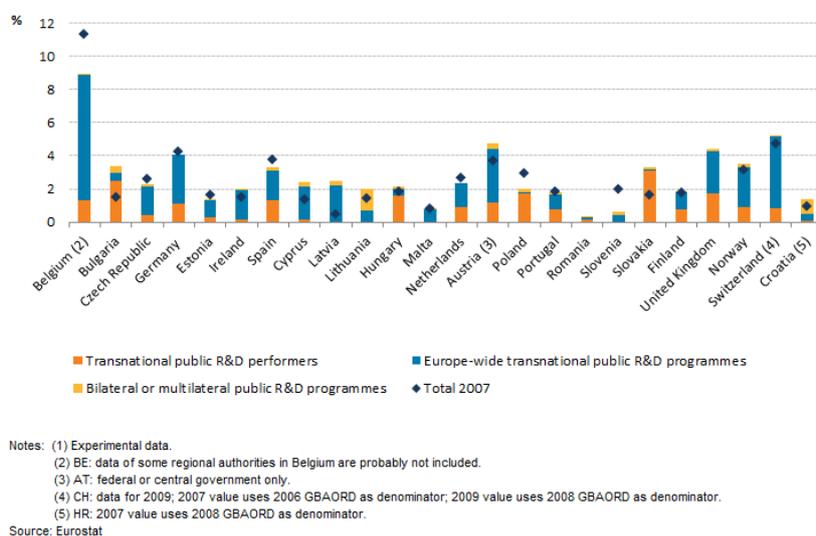

Figure 1: National public funding to transnationally coordinated research, by category, 2010(1) (as a% of total national GBAORD)

Country	National public funding to transnationally coordinated research					Share of national public funding to transnationally coordinated research in total GBAORD

Table 2: National public funding to transnationally coordinated research, 2010

Main statistical findings

(from the third round of experimental data collection 2012)

- **On average, about 3.8% of EU Member States' R & D budget was directed to 'transnationally coordinated research' in 2010**

In 2010, for the 21 EU Member States providing these data except Belgium, the share of the total R & D budget (GBAORD) that was used to fund 'transnationally coordinated research' ranges from 0.27% in Romania to 4.76% in Austria, with an EU aggregate of 3.79% (based on the data for 21 Member States). Belgium stands out as an exceptional case, with 8.95% of its R & D budget directed to transnationally coordinated research in 2010.

- **The share of countries' R & D budget directed to 'transnationally coordinated research' decreased slightly in 2010 compared to 2009**

Between 2009 and 2010 the share of the R & D budget directed to 'transnationally coordinated research' increased most significantly in Bulgaria (from 1.50% to 3.39%) and Malta (from 0.25% to 0.81%). It decreased noticeably in Estonia (from 5.21% to 1.31%) and Slovenia (from 2.80% to 0.60%). At EU aggregate level (for the 21 Member States that provided the data on this indicator) it decreased slightly from 3.84%, in 2009 to 3.79% in 2010. In nominal terms national public funding to transnationally coordinated research increased in most of the countries except Estonia, Spain, Latvia, Lithuania, Hungary and Slovenia.

- **Framework Programme instruments for coordinating national R & D programmes and other Europe-wide R & D programmes are a major driving force for transnationally coordinated research activities**

In the majority of the countries that provided data, the largest share of the national contributions to transnationally coordinated research goes to the category 'Europe-wide transnational public R & D programmes'. In Bulgaria, Hungary, Poland, Romania and Slovakia, the dominant category is 'transnational public R & D performers'. In Lithuania and Croatia 'bilateral or multilateral public R & D programmes' registered the highest share.

The observations show the considerable importance of Europe-wide programmes in steering coordinated research in European countries. The use of Framework programme (FP) coordination instruments in particular (participation in ERA-NETs, European Technology Platforms, Joint Technology Initiatives) and coordination under the [ESFRI Roadmap](#), are mentioned in all countries as major vehicles for implementing S & T and research coordination (*Monitoring progress towards the ERA*, European Commission, [ERAWATCH Network](#), 2009).

Data sources and availability

The third round of data collection on 'national public funding to transnationally coordinated research' was conducted in 2012 by national statistical institutes under the guidance of [Eurostat](#). As it is still an experimental data collection of this kind, the figures have to be viewed with the utmost caution and will be subject to revision in the coming years. Twenty four European countries, including 21 EU Member States, provided comprehensive data on this indicator.

The main source used by most of the countries for the compilation of these data is 'government budget appropriations or outlays for research and development (GBAORD)', in many cases supplemented with additional information from the national funding agencies/ministries. In some countries, R & D budget text analysis is combined with data collected through R & D surveys.

GBAORD covers not only government-financed R & D performed in government establishments, but also government-financed R & D in the other three national sectors (business enterprise, private non-profit, higher education) as well as abroad (including international organisations).

Transnational public R & D performers include:

- the [European Organisation for Nuclear Research \(CERN\)](#) ;
- the [European Molecular Biology Laboratory \(EMBL\)](#) ;
- the [European Southern Observatory \(ESO\)](#) ;
- the [European Synchrotron Radiation Facility \(ESRF\)](#) ;
- the [Institut Laue-Langevin \(ILL\)](#) ;
- the [European Commission](#) 's [Joint Research Centre \(JRC\)](#) .

Europe-wide transnational public R & D programmes include: [EUREKA](#) , [COST](#), [ESA](#), [ERA-NETs](#) , [ERA-NET+](#), [EFDA](#) , [EUROCORES](#) , Article 185 initiatives (Europe-developing countries clinical trials platform, Eurostars and Ambient assisted living for the elderly), Joint technology initiatives (public funding part: ENIAC, ARTEMIS). National contributions to FP funding which come from the overall national contributions to the total EU budget are not included in the data provided in Tables 1 and 2.

Bilateral or multilateral public R & D programmes established between Member State governments include: non-EC funded public R & D programmes jointly undertaken by the governments of at least two Member States, Candidate countries or EFTA countries, although other non-EU countries can also participate in them.

National public funding of transnationally coordinated research is measured as the 'government budget appropriations or outlays for research and development (GBAORD)' directed towards three categories of R & D performers and programmes:

1. transnational public R & D performers located in Europe;
2. Europe-wide transnational public R & D programmes;
3. bilateral or multilateral public R & D programmes established between Member State governments (and with candidate countries and EFTA countries).

While the first category often involves cross-border flows of funds (the transnational R & D performer being located in one country is located abroad for all the other contributing countries), this is not the case for the second and third categories, which may or may not involve cross-border flows of funds. In most transnational R & D programmes, there is actually no cross-border flow of funds, as each country funds its own participants.

Transnationally coordinated research is not meant to be limited to European coordination only. Naturally, non-European countries participate in research activities performed by transnational public R & D performers located in Europe. Multilateral public R & D programmes between European countries can (and often do) include non-European countries.

Context

Transnationally coordinated public R & D activities are a key element and are growing in importance for the development of the European Research Area (ERA).

Over the past fifty years, Europe has been successful in establishing effective publicly-funded mechanisms for transnational cooperation in research. Various intergovernmental research organisations have been created, such as the European Organisation for Nuclear Research (CERN), the European Molecular Biology Laboratory (EMBL) and the European Space Agency (ESA). The European Commission's Joint Research Centre has also emerged as an important R&D player. In the 1970s and 1980s, inter-governmental schemes such as COST and EUREKA were launched and the EU Framework programme for research was initiated.

In recent years new forms of transnational cooperation have started to emerge. Since 2005, the European Union has launched new instruments of coordination and collaboration known as ERA-NET and Article 185 initiatives. European countries will also be investing heavily in the ITER project, along with their international partners. In addition, European countries are now cooperating to fund and build the next wave of European

(and international) research infrastructures, and 35 new pan-European infrastructures have already been identified by the intergovernmental body ESFRI.

In order to improve policy for the ERA, it is important to know what amount of public research effort in the ERA involves these (or other) forms of transnational cooperation, since the manner in which R & D funding is allocated has important implications for the achievement of the ERA objectives. In an effort to respond to this need, Eurostat carried out the third round of experimental data collection on 'national public funding to transnationally coordinated research' in 2012.

Table 3: Gross domestic expenditure on R&D by source of funds, 2005 and 2010(% of total gross expenditure on R&D) - Source: Eurostat (tsc00031), OECD

This article presents data on [research and development \(R&D\)](#) expenditures within the [European Union \(EU\)](#), according to the sector of performance and the source of funds. The data are obtained through statistical surveys which are regularly conducted at national level covering R&D performing entities in the private and public sectors.

One of the key objectives of the EU during the last decade has been to encourage increasing levels of investment, in order to provide a stimulus to the EU's competitiveness. The Lisbon strategy set the EU an objective of devoting 3% of its GDP to R&D activities by 2010. The target was not reached – and subsequently the 3% target was maintained, forming one of five key targets within the [Europe 2020 strategy](#) adopted in 2010.

Main statistical findings

Gross domestic expenditure on R&D (GERD) stood at EUR245673 million in the EU-27 in 2010, which was a 3.8% increase on the year before, and some 43.5% higher than ten years earlier (in 2000) – note that these rates of change are in current prices and so reflect price changes as well as real changes in the level of expenditure. In 2008 the level of expenditure on R&D in the EU-27 was 88.5% of that recorded by the United States, although slightly more than double the level of expenditure in Japan and considerably above R&D expenditure levels recorded in the emerging economies – for example, EU-27 expenditure was 5.3 times as high as in China.

In order to make figures more comparable, GERD is often expressed relative to [gross domestic product \(GDP\)](#)

– see Figure 1 – or in relation to population. The ratio of GERD to GDP, one of five key Europe 2020 strategy indicators, increased marginally in the EU-27 during the period up to 2002 reaching a high of 1.88%, before declining modestly through to 2005 (1.83%), and climbing again to 2.01% by 2009. There was a small decline in 2010 when the ratio fell to 2.00%. The decrease – despite the higher absolute level of R&D expenditure – was due to the partial recovery from the financial and economic crisis, as GDP increased at a slightly faster pace than GERD in 2010. Nevertheless, the EU-27's R&D expenditure relative to GDP remained well below the corresponding shares recorded in Japan (3.45%) and the United States (2.79%) in 2008; this pattern has existed for a lengthy period of time. There was a far higher increase in the relative importance of GERD in the Japanese economy, as its share of GDP rose by 0.41 percentage points during the period 2000 to 2008; note however that Japanese economic growth was also subdued during this period.

Among the EU Member States, the highest R&D intensities in 2010 were recorded in Finland (3.87%), Sweden (3.42%) and Denmark (3.06%) – see Table 1. There were eight Member States that reported R&D expenditure accounting for less than 1% of their GDP in 2010; Greece also had a ratio of less than 1% although its latest available data is for 2007. The Member States with the lowest R&D intensity were generally in southern and eastern Europe.

The differences in the relative importance of R&D expenditure between countries are often explained by referring to levels of expenditure within the business enterprise sector. Table 2 shows that the share of R&D conducted within the business enterprise sector was equivalent to 1.23% of the EU-27's GDP in 2010, compared with 2.70% in Japan and 2.02% in the United States (both 2008), while the relative importance of R&D expenditure in the government and higher education sector was broadly similar across all three members of the [Triad](#). An evaluation of the data for the EU Member States also confirms that those countries with relatively high shares of business enterprise expenditure on R&D – namely, Finland, Sweden, Denmark, Austria and Germany – also reported relatively high levels of total GERD. Apart from Germany, these countries also tended to feature near the top-end of the ranking of expenditure by the higher education sector, where the Netherlands also had a relatively high share of R&D expenditure. Government R&D expenditure relative to GDP was highest in Germany, Slovenia, France and Finland.

An analysis of R&D expenditure by source of funds shows that more than half (54.1%) of the total expenditure in 2009 within the EU-27 was funded by business enterprises, while just over one third (34.9%) was funded by government, and a further 8.4% from abroad (foreign funds). Business-funded R&D accounted for 78.2% of total R&D expenditure in Japan and 67.3% in the United States (both 2008). Table 3 confirms the relatively important role played by the business enterprise sector as a source of R&D funding in Luxembourg, Finland and Germany (latest available data for 2009), as business-funded R&D accounted for about two thirds of total GERD in 2010. In contrast, a majority of the gross expenditure on R&D made in Cyprus (2009), Bulgaria (2009), Poland, Romania, Slovakia and Lithuania in 2010 was funded by the government sector. There were also considerable differences in the source of R&D funding from abroad, with relatively high shares (in excess of 15% of total GERD in 2010) reported in Latvia, Lithuania, Malta, Austria, the United Kingdom and Ireland (2009).

Data sources and availability

Statistics on science, technology and innovation are based on [Decision 1608/2003/EC](#) of the European Parliament and of the Council concerning the production and development of Community statistics on science and technology. The Decision was implemented by the European Commission as [Commission Regulation 753/2004](#) on statistics on science and technology which was adopted in 2004 following close cooperation with the EU Member States.

Eurostat's statistics on R&D expenditure are compiled using guidelines laid out in the [Frascati manual](#), published in 2002 by the [OECD](#). R&D expenditure is a basic measure that covers intramural expenditure, in other words, all expenditures for R&D that are performed within a statistical unit or sector of the economy in the Member States.

The main analysis of R&D statistics is by four institutional sectors of performance. These four sectors are the business enterprise sector, the government sector, the higher education sector, and the private non-profit sector (the latter is not shown in this article). Gross domestic expenditure on R&D (GERD) is composed of expenditure from each of these four sectors. Expenditure data considers the research spend on the national territory, regardless of the source of funds; data are usually expressed in relation to GDP; this ratio is often

referred to as R&D intensity. Additional analysis of R&D expenditure are available by: source of funds; field of science; type of costs; economic activity ([NACE](#)); enterprise size class; type of R&D; socio-economic objectives; and regions ([NUTS](#)).

Context

The European Commission has through its [innovation union](#) flagship initiative (which forms part of the Europe 2020 strategy) placed renewed emphasis on the conversion of Europe's scientific expertise into marketable products and services, through seeking to use public sector intervention to stimulate the private sector and to remove bottlenecks which stop such ideas reaching the market. Furthermore, the latest revision of the [integrated economic and employment guidelines](#) (revised as part of the [Europe 2020 strategy](#)) includes a guideline to optimise support for R&D and innovation, strengthening the knowledge triangle and unleashing the potential of the digital economy.

The [European Commission](#) compiles three levels of [indicators to support research and innovation policymaking](#) . These may be grouped together as: the headline indicator; innovation union scoreboard (or core) indicators; and a comprehensive set of other indicators. The headline indicator is the 3% target for research intensity to be reached within the EU by 2020; this is one of five Europe 2020 headline indicators being tracked within the Europe 2020 strategy. The scoreboard indicators are designed to monitor research and innovation for the Competitiveness Council, while the comprehensive set of other indicators are for in-depth economic analytical purposes and Commission services to produce a science, technology and competitiveness report.

One area that has received considerable attention in recent years is the structural difference in R&D funding between Europe and its main competitors. Policymakers in Europe have tried to increase R&D business expenditure so that it is more in line with relative contributions observed in Japan or the United States. The [European Research Area \(ERA\)](#) is designed to overcome some of these barriers that are thought to have hampered European research efforts, for example, by addressing geographical, institutional, disciplinary and sectoral boundaries.

In December 2008, the Competitiveness Council adopted a [2020 vision for the ERA](#) . According to the opening statement of this vision, all players should benefit from: the 'fifth freedom', introducing the free circulation of researchers, knowledge and technology across the ERA; attractive conditions for carrying out research and investing in R&D intensive sectors; Europe-wide scientific competition, together with the appropriate level of cooperation and coordination. The 2020 vision for the ERA is part of the wider picture of Europe's 2020 strategy for smart, sustainable and inclusive growth.

In November 2011 the European Commission presented a successor for the [7th Framework Programme](#) by announcing [Horizon 2020](#) , an EUR80000 million programme for investment in research and innovation, implementing the innovation union. Horizon 2020 focuses on turning scientific breakthroughs into innovative goods and services that have the potential to provide business opportunities and change people's lives for the better. Running from 2014 to 2020 this programme is part of the EU's drive to create new growth and jobs in Europe.

Source: Eurostat (online data code: educ_enr15)

Table 4: PhD students(ISCED level 6), 2010 - Source: Eurostat (educ_enr15)

This article analyses data on [research and development \(R&D\) personnel, researchers](#) and human resources in science and technology (HRST) in the [European Union \(EU\)](#) . Statistics on science and technology personnel

are key indicators for measuring the knowledge-based economy and its developments, for example, providing information on the supply of, and demand for, highly qualified science and technology specialists.

Main statistical findings

R&D personnel

The number of [researchers](#) in the [EU-27](#) has increased in recent years. There were 1.56 million researchers (in [full-time equivalents \(FTE\)](#)) employed in the EU-27 in 2010 (see Table 1), which marked an increase of almost 446000 (or 40%) when compared with 2000.

An analysis of R&D personnel in the EU-27 by [institutional sector](#) in 2010 shows that there was a high concentration of researchers in the business enterprise sector (45%) and the higher education sector (41%), while 13% of the total number of researchers were working in the [government sector](#) . The relative importance of the different institutional sectors varied considerably across the EU Member States, with business enterprises accounting for more than three fifths of all researchers in Austria, Sweden and Denmark. Bulgaria reported that more than half (53%) of its researchers were employed within the government sector, far more than the next highest share recorded in Romania (28%). More than two thirds of all researchers working in Latvia, Lithuania and Slovakia were employed within the higher education sector, and more than half of the total number of researchers worked in the higher education sector in Portugal, Poland, the United Kingdom, Greece (2007), Cyprus and Estonia.

R&D personnel from all sectors together made up more than 2.0% of the [labour force](#) in Luxembourg and Finland in 2010. Aside from these two Member States, this share ranged from less than 0.5% in Romania, Cyprus, Poland, Latvia, and Bulgaria to over 1.5% in Sweden and Denmark with the EU-27 average at an estimated 1.04% (see Figure 1).

A analysis of researchers broken down by sex shows that men accounted for 70% of the EU-27's workforce in 2009, three percentage points less than in 2000. Women accounted for exactly half of the total number of researchers in 2009 in Latvia and Lithuania, and their share was very close to parity in Bulgaria and Croatia (see Figure 1).

Human resources in science and technology

Human resources in science and technology (HRST) provide a broad measure of the supply of, and demand for, people who are highly qualified and/or are working in science and technology occupations. Some 71.7 million people were employed in the EU-27 within science and technology occupations in 2011; this amounted to one third (33.2%) of total [employment](#) . Between 2008 and 2010 there was an increase in the relative importance of HRST by occupation within the EU-27 workforce, as their share rose by 0.9 percentage points; a comparison of the share in 2011 with earlier years is unreliable because of a break in series – see Table 2. The HRST 'core' – which is made up of people within science and technology occupations who possess a [tertiary level education](#) (for example, university graduates) – amounted to 44.3 million persons in 2011 across the whole of the EU-27, or just over one fifth (20.5%) of the total number of persons employed.

Persons in HRST occupations accounted for just over half of the workforce in Luxembourg in 2011, and for around two fifths of the total in Sweden, Denmark and the Netherlands. The lowest shares were recorded in Romania, Portugal and Bulgaria, the only EU Member States to report that less than one quarter of the workforce was employed in HRST occupations. Concerning core HRST, in other words persons simultaneously in HRST occupations and having completed a tertiary level of education, the range between countries was similar: Romania, Italy and Austria were the only EU Member States to report that less than 15.0% of those employed were core HRST in 2011, while at the other end of the scale this share rose to 35.3% in Luxembourg (see Table 2).

Within the EU-27 there were 12.5 graduates from mathematics, science and technology fields of education per 1000 persons aged 20 to 29 years in 2010, with particularly high ratios – above 20 graduates per 1000 persons – being recorded in Finland, France (2009) and Ireland (see Table 3). This ratio should be interpreted with care as some graduates may be foreigners who return home following their studies and so push up the ratio in the country where they studied and pull down the ratio in their country of origin; this may explain to a large

extent the very low ratios recorded in the three smallest Member States, namely Luxembourg, Cyprus and Malta.

A similar but more specific measure of a country's potential research capability is provided by the number of doctoral students (see Table 4). There were 525800 doctoral students in the EU-27 in 2007, compared with levels of 479400 in the United States and 73700 in Japan (these latter two figures are for 2010). In relative terms, the broad subject group of science, mathematics, computing, engineering, manufacturing and construction-related studies accounted for more than one third (36.4%) of the doctoral students in the EU-27 in 2007, a proportion that was somewhat higher than in Japan (31.3%, again for 2010) but lower than in the United States (38.2%, also for 2010).

Women accounted for 47.8% of doctoral students in the EU-27 in 2007, a share that was not too dissimilar from that recorded in the United States, where women were on a par with men (49.9% in 2010); in contrast, men accounted for a much higher share of doctoral students in Japan (67.9% in 2010). The gender split of doctoral students across the Member States was typically quite balanced in 2010 (no data available for Germany): women accounted for more than half of all the doctoral students in the [Baltic Member States](#), Portugal, Italy, Finland, Poland, Cyprus, Spain, Slovenia and Bulgaria, and at least 40% of all doctoral students in the remaining Member States, with the exception of Malta.

Data sources and availability

Statistics on science, technology and innovation are based on [Decision 1608/2003/EC](#) of the European Parliament and the Council concerning the production and development of Community statistics on science and technology. The Decision was implemented by the European Commission as Commission [Regulation 753/2004](#) on statistics on science and technology which was adopted in 2004 following close cooperation with the EU Member States.

Statistics on R&D personnel are compiled using guidelines laid out in the [Frascati manual](#), published in 2002 by the [OECD](#). R&D personnel include all persons employed directly within R&D, as well as persons supplying direct services (such as managers, administrative staff and clerical staff). For statistical purposes, indicators on R&D personnel are compiled as both head counts (HC) and as full-time equivalents (FTEs). Researchers are a sub-category of R&D personnel and are professionals engaged in the conception or creation of new knowledge, products, processes, methods and systems, and in the management of the projects concerned.

Statistics on human resources in science and technology (HRST) are compiled using guidelines laid out in the [Canberra manual](#), prepared in cooperation between the OECD, [European Commission](#), [UNESCO](#) and the [International Labour Organisation](#), and published in 1995. HRST are defined on the basis of education and/or occupation. HRST based on education are persons having successfully completed tertiary education in one or more of seven broad fields: natural sciences, engineering and technology, medical sciences, agricultural sciences, social sciences, humanities, and other fields. HRST based on occupation are persons who are employed in science and technology occupations as professionals or technicians. Persons who fulfil both education and occupation criteria are classified as the HRST 'core'. Tertiary education is defined as levels 5a, 5b or 6 of the 1997 version of the [international standard classification of education \(ISCED\)](#). In November 2011, UNESCO completed work on a revised ISCED classification ([ISCED 2011](#)); note that the first data collection based on the new classification will not begin until 2014. Among other changes, ISCED 2011 proposes four levels of tertiary education compared with two in ISCED 1997. Another means of classifying science and technology personnel based on occupation relates to 'professionals' and 'technicians and associate professionals' within the international standard classification of occupations (ISCO). Starting with reference year 2011, a new version of ISCO ([ISCO-08](#)) has been implemented. There is no one-to-one correspondence between the two versions of ISCO: [ISCO-88](#) and ISCO-08, resulting in a break in series between 2010 and 2011. However, the definition of the HRST population based on occupation remains broadly the same on the basis of the definitions for the two major groups (Group 2 - 'Professionals' and Group 3 - 'Technicians and associate professionals').

HRST data can be analysed by sex, age, region, sector of activity, occupation, educational attainment and fields of education (although it should be noted that not all combinations are possible). Data relating to stocks of HRST provide information on the characteristics of the current labour force.

Information on HRST flows from education are obtained from a UNESCO/OECD/Eurostat questionnaire on education and this can be used to provide a measure of the current and future supply of HRST from the edu-

cation system, in terms of actual inflows (graduates from the reference period) and potential inflows (students participating in higher education during the reference period). Science and technology graduates are defined as the number of new graduates from all public and private institutions completing science and technology-related graduate and post-graduate studies in the reference year; the number of graduates may be expressed relative to the total number of persons aged 20-29 years.

Indicators based on the number of doctoral students give an idea of the extent to which countries will have researchers at the highest level of education in the future. The data relate to the number of students in the reference year; they do not refer to the number of new graduates or to the total number (stock) of graduates in the labour market that year. The number of doctoral students is measured as students enrolled in ISCED level 6: this level concerns tertiary programmes which lead to the award of an advanced research degree, for example, a doctorate in economics. These programmes should be devoted to advanced study and original research and are not based on course-work alone; studies at the doctoral level usually require 3 to 5 years.

Context

The [European Research Area \(ERA\)](#) is composed of all research and development activities, programmes and policies in Europe which involve a transnational perspective. In May 2008, the European Commission adopted a Communication to launch an initiative titled, ' [better careers and more mobility: a European partnership for researchers](#) ' (COM(2008) 317 final). The goal of this initiative is to improve the mobility of researchers and to enhance the diffusion of knowledge throughout Europe, by: balancing demand and supply for researchers at a European level; helping create centres of excellence; and improving the skills of researchers in Europe.

In December 2008, the Competitiveness Council adopted a [2020 vision for the ERA](#) . According to the opening statement of this vision, all players should benefit from: the 'fifth freedom', introducing the free circulation of researchers, knowledge and technology across the ERA; attractive conditions for carrying out research and investing in R&D intensive sectors; Europe-wide scientific competition, together with the appropriate level of cooperation and coordination. The 2020 vision for the ERA is part of the wider picture of [Europe's 2020 strategy](#) for smart, sustainable and inclusive growth.

As part of the [EU's 7th framework programme for research and technological development \(FP7\)](#) the European Commission announced in July 2011 nearly EUR7000 million of investment in research and innovation, with the aim of providing an economic stimulus expected to create around 174000 jobs.

In the FP7 the Marie Curie actions have been regrouped and reinforced within the specific programme titled [people](#) . Entirely dedicated to human resources in research, this programme has an overall budget of more than EUR4700 million over a seven-year period until 2013. Within the programme, efforts will be made to increase participation by women researchers, by encouraging equal opportunities, by designing actions to ensure that researchers can achieve an appropriate work/life balance, and by making it easier to resume a research career after a break from work. There are a number of bodies actively promoting greater gender equality, including: the European association for women in science, engineering and technology ([WiTEC](#)) and the European platform of women scientists ([EPWS](#)) .

Science and technology introduced

Latest update of text: October 2012

Science is part of almost every aspect of our lives: at the flick of a switch, we have light; when we are ill, medicines help us get better; when we want to talk to a friend we just pick up the telephone or send a text message or e-mail. Europe has a long tradition of excellence in research and [innovation](#), having been the birthplace of the industrial revolution. The [European Union \(EU\)](#) is a world leader in a range of cutting-edge industrial sectors – for example, biotechnology, pharmaceuticals, telecommunications or aerospace.

[Research and development \(R&D\)](#) is often considered as one of the driving forces behind growth and job creation. However, its influence extends well beyond the economic sphere, as it can potentially resolve environmental or international security threats, ensure safer food, or lead to the development of new medicines to fight illness and disease.

Framework programmes

While most research within the EU is funded on a national level by private and public sources, since their launch in 1984, the EU's framework programmes for research have played a leading role in multidisciplinary research activities. The [seventh framework programme for research and technological development \(FP7\)](#) is the EU's main instrument for funding research across Europe; it runs from 2007 to 2013 and has a total budget of EUR50521 million, with an additional EUR2751 million for 2007 to 2011 for nuclear research and training activities to be carried out under the [Euratom Treaty](#). This money is generally intended to finance grants to research actors all over Europe, usually through co-financing research, technological development and demonstration projects. FP7 is made up of four broad programmes – cooperation (collaborative research), ideas (the [European Research Council](#)), people (human potential) and capacities (research capacity). Through these programmes, FP7 aims to create European 'poles of excellence' across a wide array of scientific themes, such as information technologies, energy and climate change, health, food, and social sciences. FP7 also foresees direct research at the [European Commission](#)'s own research institute (the [Joint Research Centre \(JRC\)](#)), whose activities are divided into 17 policy agendas, with an emphasis on understanding the relationship between the environment and health, internal and external security, and support for [Europe's 2020 growth strategy](#).

[Horizon 2020](#) is planned as the framework programme for research and innovation for the period running from 2014 through to 2020, building upon FP7, the competitiveness and innovation framework programme (CIP) and the European institute of innovation and technology (EIT). A Green paper titled '[From challenges to opportunities: towards a common strategic framework for EU research and innovation funding](#)' (COM(2011) 48 final) was adopted by the European Commission in February 2011 and proposed major changes to EU research and innovation funding to make participation easier, increase scientific and economic impact and provide better value for money. Preparatory work to bring about the new framework programme advanced during 2011, as the European Commission made a number of proposals, including proposals for Regulations of the European Parliament and Council to [establish the framework programme](#) (COM(2011) 809 final) and [to lay down rules for the participation and dissemination of Horizon 2020](#) (COM(2011) 810 final), a proposal for a Council Decision [establishing the specific programme implementing Horizon 2020](#) (COM(2011) 811 final) and a proposal for a Council Regulation on the [research and training programme of the European Atomic Energy Community \(2014-2018\) complementing Horizon 2020](#) (COM(2011) 812 final).

European Research Area

The [European Research Area \(ERA\)](#) was launched at the [Lisbon European Council](#) in March 2000. ERA aims to ensure open and transparent trade in scientific and technical skills, ideas and know-how. Europe's research efforts are often described as being fragmented along national and institutional lines. Indeed, individual EU Member States may find it difficult to play a leading role in important areas of scientific and technological advance as research is increasingly complex, interdisciplinary and expensive.

The ERA was given new impetus in April 2007 with the European Commission's Green paper on [the European research area: new perspectives](#) (COM(2007) 161 final). In May 2008, the ERA was re-launched as

part of what has become known as the [Ljubljana process](#) , including specific initiatives for five different areas: researchers' careers and mobility; research infrastructures; knowledge sharing; research programmes; and international science and technology cooperation. As a result, in the years through to 2020 the ERA will aim to establish a single European labour market for researchers, as well as single markets for knowledge and for innovative goods and services. Furthermore, the ERA should aim to: encourage trust and dialogue between society and the scientific and technological community; benefit from a strong publicly-supported research and technology base and world-class research infrastructures and capacities across Europe; provide for the joint design of research, education and innovation policies; address major challenges through strategic partnerships; and enable Europe to speak with one voice to its main international partners.

International cooperation forms an integral part of the EU's scientific policy, which includes programmes to enhance Europe's access to worldwide scientific expertise, attract top scientists to work in Europe, contribute to international responses to shared problems, and put research at the service of EU external and development policies. In December 2008, the Competitiveness Council adopted a [2020 vision for the ERA](#) , which foresees the introduction of a 'fifth freedom' for the EU's internal market – namely, the free circulation of researchers, knowledge and technology.

In July 2012, a Communication from the European Commission titled ' [A reinforced European Research Area Partnership for Excellence and Growth](#) ' (COM(2012) 392 final) was released. This aims to promote a significant improvement in Europe's research performance, stimulating growth and job creation. The measures in the Communication are designed to ensure the completion of the ERA by 2014, through various measures which need to be implemented by EU Member States, the European Commission and research organisations.

Innovation union

In October 2010, the European Commission launched a [Europe 2020](#) flagship initiative, titled ' [Innovation union](#) ' (COM(2010) 546 final) which sets out a strategic approach to a range of challenges like climate change, energy and food security, health and an ageing population. The proposals seek to use public sector intervention to stimulate the private sector and to remove bottlenecks which stop ideas reaching the market (such as access to finance, fragmented research systems and markets, under-use of public procurement for innovation, and speeding-up harmonised standards and technical specifications). In December 2011, the European Commission released the ' [State of the innovation union 2011](#) ' (COM(2011) 849 final), which reviewed progress made with respect to the 34 commitments made in the innovation union. European Innovation Partnerships (EIPs) also form part of the innovation union and are designed to act as a framework to address major societal challenges, bringing together activities and policies from basic research through to market-oriented solutions – for more information, see the article on [innovation statistics](#) .

International statistics

Official European statistics on science and technology provide a leading example of cooperation activities between international statistical organisations. In the domain of R&D statistics a joint survey produced by the [OECD](#) and [Eurostat](#) has been introduced, which is based on the collection of information following guidelines laid out in the [Frascati manual](#) . As regards human capital, Eurostat participated in the first two rounds (2006 and 2009) of a joint international survey – with the OECD and [UNESCO](#) aimed at developing internationally comparable indicators on the careers and mobility of doctorate (PhD) holders ([CDH statistics](#)). Within the domain of innovation statistics, Eurostat conducts a [Community innovation survey](#) , which is based on the guidelines laid out within the [Oslo manual](#) (jointly produced with other European Commission services and the OECD). In the framework of the International Patent Statistics Task Force (gathering the [European Patent Office \(EPO\)](#) , the [United States Patent and Trademark Office \(USPTO\)](#) , the OECD, the [World Intellectual Property Organization \(WIPO\)](#) , the [Japan Patent Office \(JPO\)](#) , the [Korean Intellectual Property Office \(KIPO\)](#) and the [United States National Science Foundation \(NSF\)](#)), Eurostat has worked towards the improvement of [PATSTAT](#) , a harmonised database held by EPO and covering EPO [patent applications](#) and USPTO patents granted.

The innovation scoreboard used for assessing innovation performance in the EU Member States has been re-worked to improve international comparability and to include a number of research-oriented indicators in line with the purpose of monitoring the implementation of the innovation union; it has been renamed the [innovation](#)

[union scoreboard](#) . This revised tool aims to provide a comparative assessment of the performance of the EU Member States and ten global competitors and the relative strengths and weaknesses of their research and innovation systems. The 2011 scoreboard is based on 25 research and innovation-related indicators grouped into three main categories and eight innovation dimensions, covering:

- enablers such as human resources, finance and support, open, excellent and attractive research systems;
- activities of enterprises, such as investment, linkages and entrepreneurship or intellectual assets; and
- outputs, such as innovators and economic effects.

Science and technology statistics at regional level

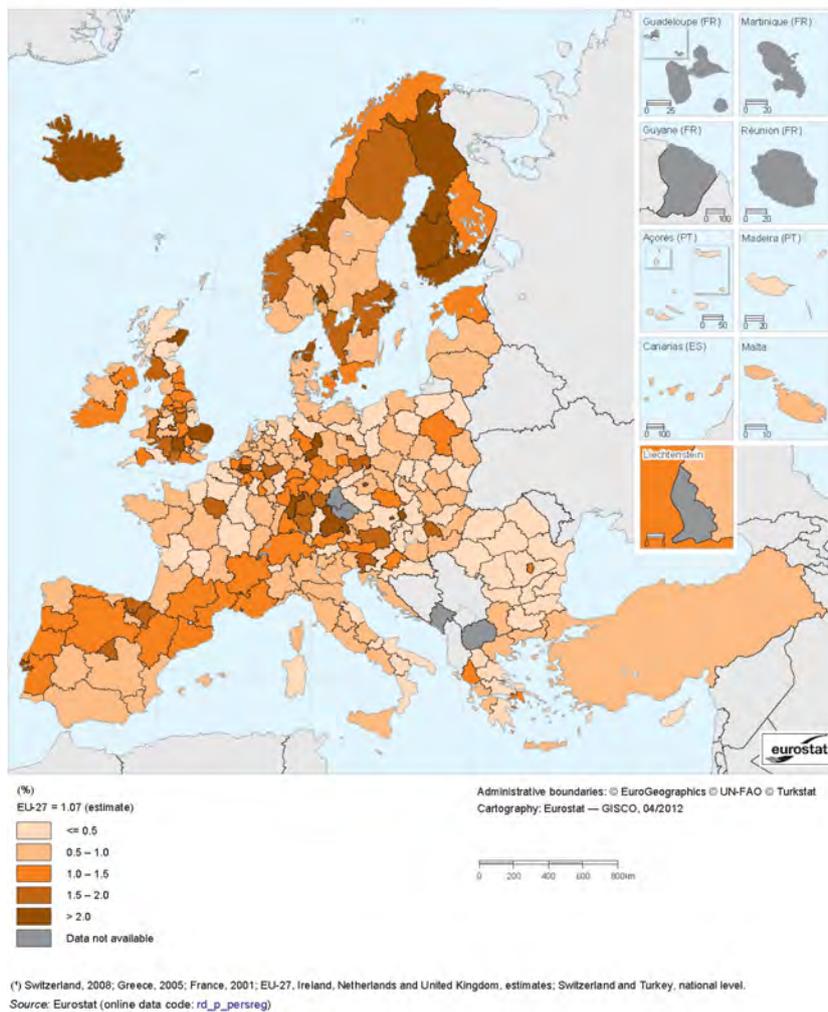

Data from February 2012. Most recent data: Further Eurostat information, Main tables and Database .

This article presents statistical information that illustrates regional developments for science and technology indicators within the [European Union \(EU\)](#) . The domains covered are [research and development \(R&D\)](#) , the number of [researchers](#) , [human resources in science and technology \(HRST\)](#) , employment in [high technology](#) sectors and [patent applications](#) .

Main statistical findings

Research and development intensity

The EU-27 had an **R&D intensity** ratio of 2.01% in 2009, in other words, **expenditure on R&D** was equivalent to 2.01% of **GDP**. A total of 35 of the 266 EU regions shown in Map 1 had R&D intensity above 3% in 2009. As such, they exceeded the 3% R&D intensity target set by the Barcelona Council in 2002 and maintained in the **Europe 2020** strategy. Among these 35 regions, 11 were in Germany, eight in the United Kingdom, four in Sweden, three each in Denmark and Finland and two each in Belgium, France and Austria. Together these 35 regions accounted for 45.0% of all R&D expenditure in the EU.

The German regions included a cluster of regions in south western and south eastern Germany: Rheinhesen-Pfalz, Stuttgart, Karlsruhe, Tübingen, Oberbayern, Mittelfranken and Darmstadt. These regions were also very important in absolute terms (the level rather than the intensity of R&D), as together they accounted for 13.4% of total R&D expenditure in the EU in 2009. The four other German regions with R&D intensity above 3%, from west to east, were Köln, Braunschweig (7.93% R&D intensity — the most R&D-intensive region on the map), Berlin and Dresden; these four regions together contributed 5.2% of total R&D expenditure in the EU.

The two Belgian regions were the Province/Provincie du Brabant Wallon, which was the second most R&D intensive region on the map, with a ratio equivalent to 7.6% of GDP, and the neighbouring Province/Provincie Vlaams-Brabant; as well as a large industrial area around the Belgian capital, these regions include the university towns of Louvain-la-Neuve (which has a science park) and Leuven.

Ten of the most R&D-intensive regions in 2009 were located in the **Nordic Member States**, including the capital city regions of Denmark and Sweden; the third highest R&D intensity of all EU regions was recorded in the Finnish region of Pohjois-Suomi (6.58%). The ten regions in Nordic Member States with an R&D intensity above 3% collectively contributed 9.3% of total R&D expenditure in the EU.

The two most R&D-intensive regions in the United Kingdom in 2009 were Cheshire in north west England (6.51%) and East Anglia (5.59% — this region includes the area around Cambridge). Together these two regions contributed around 2.0% of total R&D expenditure in the EU. Apart from North Eastern Scotland (which

is the main British region that supports the North Sea extraction of oil and gas) the other R&D-intensive regions in the United Kingdom were generally in southern England; together these contributed 3.9% to total R&D expenditure in the EU. In France the highest R&D intensity was in Midi-Pyrénées (4.38% — this region includes a cluster of R&D-intensive enterprises related to aerospace manufacturing centred on Toulouse) ahead of the capital city region of the Île de France (3.01%). The level of R&D expenditure in these two regions was high, particularly in the Île de France region which had the highest level of R&D expenditure among any of the NUTS level 2 regions in the EU; as a result these two French regions together contributed 8.5% to total R&D expenditure in the EU. In Austria the most R&D-intensive regions were Steiermark (3.88%) and Wien (3.95%), with a combined contribution of 1.8% to total R&D expenditure in the EU.

Among EFTA countries (no regional analysis is available) Iceland had an R&D intensity of 3.11% and Norway of 1.80% in 2009, while the rate in Switzerland was 2.99% in 2008. Turkey (no regional analysis available) had an R&D intensity of 0.85% in 2009, while the Croatian region of Sjeverozapadna Hrvatska had an R&D intensity of 1.54%, far above the intensity recorded in the two other Croatian regions (also 2009).

Researchers

Map 2 provides an overview of the regional distribution of the share of researchers in total employment (measured as a [headcount](#)); the EU-27 average for this indicator was estimated to be 1.1% in 2009. Researchers are directly employed on R&D activities and are defined as 'professionals engaged in the conception or creation of new knowledge, products, processes, methods and systems and in the management of the projects concerned'.

In many Member States the location of researchers was relatively concentrated, with a small number of regions recording a relatively high share of researchers in total employment far above the national average. The share of researchers among all persons employed was more than 2.0% in 21 of the EU regions shown in Map 2. The Member States with several regions above this level included: Germany and the United Kingdom with four each, Belgium and Finland with three each, and Denmark with two. Around two thirds of these regions with a high proportion of researchers also had high R&D intensity. Nevertheless, there were five regions where researchers accounted for more than 2.0% of the workforce but where R&D intensity did not exceed 3%: the capital city regions of Belgium, the Czech Republic, Portugal, Slovakia and the United Kingdom. More than 2.0% of the workforce in Iceland and the Norwegian regions of Trøndelag and Oslo og Akershus were researchers. The share of researchers exceeded 1.5%, but was 2.0% or less, in a further 22 regions within the EU, six each of which were in the United Kingdom or Germany; several of the other ten regions were in Sweden or Spain (three regions each), while the remainder were the capital city regions of France (note that the data for France relate to 2001), Hungary and Slovenia, as well as the Steiermark region of Austria. In 77 regions, the share of researchers was 0.5% or less of all persons employed and these regions were distributed across 19 of the EU Member States.

Human resources in science and technology

Investment in research, development, education and skills are key policy areas for the EU, as they may be considered essential to economic growth and to the development of a knowledge-based and so-called 'smarter' economy. This has led to an increased interest in the role and measurement of skills of people with science and technology-related education or work. One way to measure the concentration of highly qualified people is to look at human resources in science and technology (HRST): the [stock of HRST](#) can be used as an indicator to determine how developed the knowledge-based economy is. HRST includes persons who have completed tertiary education (HRSTE) — for example, university degrees — and/or are employed in a science and technology occupation (HRSTO); the group of persons who meet both criteria are referred to as core HRST.

Map 3 focuses on the number of persons having completed a [tertiary education](#) that are employed in a science and technology (S & T) occupation, in other words, core HRST. The map shows the level of core HRST relative to the size of the labour force (the economically active population). In 2010, 15 of the 33 EU-27 regions with the highest shares of core HRST in the labour force (those exceeding 22%) were capital city regions, while the remainder were generally other urban regions. Among all of the regions in the EU, the highest share was reported in Inner London (United Kingdom) where 33.4% of the labour force was considered to be core HRST.

Beyond this concentration in capital cities, there were also relatively high share of core HRST in the German regions which included the major cities of München and Hamburg, as well as in one region bordering Berlin and in Tübingen, while in Sweden the regions with a high share covered the major cities of Malmö and Göteborg. Other regions outside of capital city regions with over 22% of their respective labour forces considered to be core HRST included the País Vasco (which includes Bilbao) in Spain and Alsace and Midi-Pyrénées (including Strasbourg and Toulouse respectively) in France. Finally, there was a cluster of regions with high shares of core HRST that stretched from Luxembourg, through south-eastern Belgium up to Oost-Vlaanderen in the north of Belgium, with two more regions in the west and north of the Netherlands around the cities of Groningen and Utrecht.

Among the EFTA countries, the highest share (36.1%) of the labour force classified as core HRST was recorded in the Norwegian capital city region of Oslo og Akershus, a higher share than in any region in the EU; five other Norwegian regions had shares over 22%. Three Swiss regions recorded shares of core HRST above 22% of the labour force, namely the Région lémanique (including the city of Genève), Nordwestschweiz (including Basel) and Zürich. Like Belgium, Switzerland was unusual in that several regions had particularly high shares of core HRST (over 22%), but not the capital city region itself, as the Espace Mittelland (including Bern) recorded a share of 18.4%.

Employment in high-tech sectors

High-tech sectors include [high-tech manufacturing](#) and [high-tech knowledge-intensive services](#), based on the activity classification [NACE](#). The distinction between manufacturing and services is made due to the existence of two different methodologies. While R&D intensities are used to distinguish between high, medium-high, medium-low and low-technology manufacturing industries, for services the proportion of the workforce that has followed a tertiary education is used to distinguish between knowledge-intensive services and less knowledge-intensive services. The service sector as a whole accounted for 69.0% of employment in the EU-27 in 2010, but only 2.7% of the total was employed in high-tech knowledge-intensive services. Around 15.9% of the persons employed in the EU-27 worked in manufacturing, although the proportion that worked in high-tech manufacturing was around 1.1%. When combined, these high-tech sectors accounted for 3.7% of all employment in the EU-27.

Figure 1 shows the regional disparities in the high-tech sectors' share of total employment. This figure plots the highest and lowest shares of employment in high-tech sectors, as well as the national average and the share for the capital city region. Among those countries that have more than one NUTS level 2 region, it is clear that the share of high-tech sectors in employment varied quite substantially between regions. Urban regions, especially capital city regions or regions situated close to capitals, often exhibited the highest shares of employment in high-tech sectors. In fact, in all of the 25 multi-region countries shown in Figure 1 the employment share of high-tech sectors in the capital city region was above the national average, and in 20 of these the capital city region had the highest share; the exceptions were Belgium, Germany, the Netherlands, the United Kingdom and Switzerland.

Considering all regions in the EU-27, the share of employment in high-tech sectors was highest in Berkshire, Buckinghamshire and Oxfordshire (United Kingdom), which is situated within close proximity of London, followed by Hovedstaden (Denmark), Province/Provincie Brabant Wallon (Belgium) and Stockholm (Sweden) — these were the only regions where more than 8% of total employment was in high-tech sectors. Unlike the other indicators analysed in this article, this indicator did not show many clusters of regions within the same Member State near the top of the ranking: in fact, the ten regions with the highest shares of employment in high-tech sectors were all from different Member States. The three lowest shares among the EU regions were registered in Romania (1.0% or less of employment was in high-tech sectors), as was the case in one Spanish (Región de Murcia) and one Greek region (Dytiki Ellada).

Patents

Patent counts can provide a measure of [invention](#) and [innovation](#) and a time series of data is available with an analysis by region. However, care should be taken interpreting the data as not all inventions are patented and patent propensities vary across activities and enterprises; furthermore, patented inventions vary in technical

and economic value.

Regional patents statistics for [European Patent Office \(EPO\)](#) patent applications build on information from addresses of inventors; this is not always the place (region) of invention as inventors do not necessarily live in the same region as the one in which they work; this discrepancy is likely to be higher when smaller geographical units are used. Patent applications tend to be clustered geographically in a limited number of regions and this is especially true for high-tech activities. Map 4 shows that technological activity (based on patent applications) was very much concentrated in the centre of the EU. There were 91 NUTS level 3 regions in the EU (out of a total of 1211 regions with data available) that had more than 250 patent applications per million inhabitants in 2008. Among these were 83 German regions, two regions in Austria, France and the Netherlands, and one each in Belgium and Italy. The highest number of patents relative to inhabitants was 1251 in Erlangen (Kreisfreie Stadt) followed by 793 in the neighbouring region of Erlangen-Höchstadt; Erlangen is home to a number of research institutes, a university and various offices of the engineering group Siemens.

In the field of [information and communication technology \(ICT\)](#) patents (see Map 5) information is available for NUTS level 2 regions. Five regions within the EU had more than 100 ICT patent applications per million inhabitants in 2008, of which three were in southern Germany (Mittelfranken, Oberbayern and Freiburg) and two in Sweden (Sydsverige and Stockholm).

Figure 2 shows large differences between the top regions of each Member State in terms of the number of patents relative to the number of inhabitants in the field of high-technology. Among the 21 EU Member States with more than one region at the NUTS level 2, the highest ratio of high-tech patents to the number of inhabitants was recorded in 12 of the capital city regions. As such, high-tech patent applications were less concentrated in capital city regions than employment in high-tech sectors (see Figure 1). Furthermore, in Belgium and the Netherlands, the capital city region recorded a ratio of high-tech patents to inhabitants that was lower than the national average. Considering all EU regions together, the region of Sydsverige in Sweden had the highest number of high-tech patent applications relative to population size, 85 per million inhabitants. Two German regions (Oberbayern and Mittelfranken) and the Swedish capital city region of Stockholm followed, each with around 75 high-tech patents per million inhabitants. Nord-Brabant in the Netherlands, Oberpfalz in Germany and the capital city region of Etelä-Suomi in Finland were the only other regions in the EU with 50 or more high-tech patent applicants per million inhabitants in 2008.

Data sources and availability

[Eurostat](#) collects statistics on research and development (R&D) under the legal requirements of Commission Regulation (EC) No 753/2004, which determines the dataset, breakdowns, frequency and transmission delays. The methodology for national R&D statistics is laid down in the [Frascati manual: proposed standard practice for surveys on research and experimental development \(OECD, 2002\)](#), which is also used by many non-member countries.

Statistics on human resources in science and technology (HRST) are compiled annually, based on microdata extracted from the [EU Labour Force Survey \(EU LFS\)](#). The basic methodology for these statistics is laid down in the [Canberra manual \(OECD, 1995\)](#), which lists all the HRST concepts.

Data on high-technology manufacturing industries and knowledge-intensive services are compiled annually, based on data collected from a number of official sources (such as EU LFS and [structural business statistics \(SBS\)](#)). The high-technology manufacturing aggregates are defined in terms of R&D intensity, calculated as the ratio of R&D expenditure for an economic activity relative to its value added. For manufacturing, four groups have been identified, depending on the level of R&D intensity: high, medium-high, medium-low and low-technology sectors. Services are classified into knowledge-intensive services (KIS) and less knowledge-intensive services. High-tech knowledge-intensive services include motion picture, video and television programme production, sound recording and music publishing activities, programming and broadcasting, telecommunications, computer programming and related activities, information service activities and research and development. High-tech manufacturing covers the manufacture of pharmaceutical products and pharmaceutical preparations and of computers and electronic and optical products.

Data on patent applications to the European Patent Office (EPO) are compiled on the basis of microdata from the EPO. The patent data reported include patent applications filed at the EPO during the reference year, classified by the inventor's region of residence and in accordance with the [international patents classification](#)

of applications (IPC) . Patent data are regionalised using procedures linking postcodes and/or place names to NUTS level 2 and 3 regions. Patent statistics published by Eurostat are almost exclusively based on the [EPO Worldwide Statistical Patent Database, Patstat](#) , developed by the EPO in 2005, using its patent data collection and its knowledge of patent data.

Context

R&D is often considered as one of the driving forces behind growth and job creation. However, its influence extends well beyond the economic sphere, as it can potentially resolve environmental or international security threats, ensure safer food, or lead to the development of new medicines to fight illness and disease.

Since their launch in 1984, the EU's framework programmes for research have played a leading role in multi-disciplinary research activities. The [seventh framework programme for research and technological development \(FP7\)](#) is the EU's main instrument for funding research in Europe; it runs from 2007 to 2013 and has a total budget of EUR 50521 million, with an additional EUR 2751 for 2007 to 2011 for nuclear research and training activities to be carried out under the [Euratom Treaty](#) . FP7 aims to create European 'poles of excellence' across a wide array of scientific themes, such as information technologies, energy and climate change, health, food, and social sciences.

The [European research area \(ERA\)](#) was launched at the [Lisbon European Council](#) in March 2000. ERA aims to ensure open and transparent trade in scientific and technical skills, ideas and know-how. Europe's research efforts are often described as being fragmented along national and institutional lines. ERA was given new impetus in April 2007 with the European Commission's Green Paper on [the European research area: new perspectives](#) . In May 2008, the ERA was re-launched as part of what has become known as the [Ljubljana process](#) , which included specific initiatives for five different areas: researchers' careers and mobility; research infrastructures; knowledge sharing; research programmes; and international science and technology cooperation. As a result, in the years through to 2020 the ERA will aim to establish a single European labour market for researchers, as well as single markets for knowledge and for innovative goods and services.

In October 2010, the European Commission launched a Europe 2020 flagship initiative, titled the '[innovation union](#)' (COM(2010) 546 final); this sets out a strategic approach to a range of challenges like climate change, energy and food security, health and an ageing population. The proposals seek to use public sector intervention to stimulate the private sector and to remove bottlenecks which stop ideas reaching the market (such as access to finance, fragmented research systems and markets, under-use of public procurement for innovation, and speeding-up harmonised standards and technical specifications). European Innovation Partnerships (EIPs) form part of the innovation union and are designed to act as a framework to address major societal challenges, bringing together activities and policies from basic research through to market oriented solutions.

[Horizon 2020](#) is planned as the framework programme for research and innovation after 2013, building upon FP7, the competitiveness and innovation framework programme (CIP) and the European institute of innovation and technology (EIT). A Green Paper titled '[From challenges to opportunities: towards a common strategic framework for EU research and innovation funding](#)' (COM(2011) 48) was adopted by the European Commission in February 2011 and proposed major changes to EU research and innovation funding to make participation easier, increase scientific and economic impact and provide better value for money.

The EU in the world - science and technology

Data from June - July 2012. Most recent data: Further Eurostat information, Database .

This article is part of a [set of statistical articles](#) based on Eurostat publication *The EU in the world 2013* .

The article focuses on science and technology in the [European Union \(EU\)](#) and in the 15 non-EU countries from the [Group of Twenty \(G20\)](#) . It covers key statistics on [R & D expenditure](#) and [personnel](#) as well as [patents](#) and gives an insight into the European economy in comparison with the major economies in the rest of the world, especially with the EU's counterparts in the so-called [Triad](#) , the US and Japan, and with the [BRIC](#) countries Brazil, Russia, India and China (or [BRICS](#) if South-Africa is also included).

Main statistical findings

R & D expenditure

The highest R & D intensity among the G20 members was in South Korea

R & D includes creative work carried out on a systematic basis in order to increase the stock of knowledge of man, culture and society, and the use of this knowledge to devise new applications. **Gross domestic expenditure on research and development (GERD)** is a key measure of the level of R & D activity and encompasses expenditures in the following sectors: **business**, **higher education institutions**, **government** and **non-profit organisations**; it includes R & D that is funded from **abroad**, but excludes payments made abroad.

GERD in the **EU27** was provisionally estimated at around EUR 245.7 billion in 2010. The relation between the level of GERD and **gross domestic product (GDP)** is known as R & D intensity, and in 2010 this ratio stood at 2.00% in the EU27. According to the **United Nations Educational, Scientific and Cultural Organisation (UNESCO)**, by far the highest R & D intensity among the G20 members was in South Korea, where GERD was equivalent to 3.74% of GDP in 2010. The latest data (2008 or 2009) for Japan, the United States and Australia shows that they also recorded relatively high R & D intensities. By contrast, Saudi Arabia and Indonesia recorded by far the lowest R & D intensities among the G20 members, with GERD of less than 0.1% of GDP.

R & D intensity was higher in 2010 than in 2000 in nearly all G20 members (see Figure 1) – with only a small decline in Canada. The largest increase (in percentage point terms) in R & D intensity between 2000 and 2010 was in South Korea, with relatively large increases also recorded in Australia and China.

The increase in R & D intensity in the EU27 came mainly in recent years, as this indicator remained relatively unchanged between 2000 and 2007. Despite the financial and economic crisis there was an increase in 2008 and 2009 in the EU27's R & D intensity: in 2008 this was due to a 4.5% increase in GERD outstripping GDP growth (0.6% in current prices), while the fall in GERD (-1.2%) in 2009 was less than the sizeable contraction of GDP (-5.8%) in that year. Figure 2 shows the upward development of R & D intensity over the last ten years in the five G20 members with the highest R & D intensities.

An alternative analysis of R & D expenditure can be seen in Figure 3, namely the level of GERD relative to population size. This indicator provides a very clear distinction between G20 members; note that the data for non-member countries are also sourced from UNESCO. Japan and the United States stand out with GERD per inhabitant close to EUR 1000 in 2009. Australia, Canada, South Korea and the EU27 completed the group of countries with relatively high GERD per inhabitant. None of the other G20 members recorded GERD in excess of EUR 100 per inhabitant and this indicator dropped below EUR 10 per inhabitant in Saudi Arabia, India and Indonesia.

More than three fifths (61.5%) of all R & D in the EU27 was performed in the business enterprise sector; more than half of total R & D was performed in the business enterprise sector in most G20 members (see Table 1) although the share was lower in Mexico, Turkey, India and Argentina. The government sector was the dominant performing sector in India (61.7% of total R & D) and Argentina (44.7%), otherwise this sector performed less than one third of R & D. The higher education sector was the largest R & D

performing sector in Turkey (46.0% of the total) and exceeded one third of the total in Canada and Indonesia. Private non-profit organisations performed the smallest share of R & D in all G20 members (with data available), reaching its highest share (4.4%) in the United States.

The relative shares of R & D performance were quite different from the mix in terms of the [sources of funds](#) (see Table 2). The major difference concerned the relatively small share of funds provided by higher education institutions and the high share provided by the government sector; in other words, the R & D performed in higher education institutions was often financed by funds from other sectors, while the government sector financed far more R & D than it performed. For the business enterprise sector the shares of R & D performance and funding were relatively close in most G20 members, with the main exceptions being Russia and South Africa. Foreign financing for R & D was relatively important in South Africa where it exceeded one tenth of all financing, and to a lesser extent in the EU27 (including intra-EU cross-border funds) and Canada.

R & D personnel

The number of people working in R & D in 2009 in the EU27 was around 3.6 million

R & D personnel include all individuals employed directly in the field of R & D, covering not only [researchers](#), but also [technicians](#) and equivalent staff as well as supporting staff. The number of people working in R & D in 2009 in the EU27 was around 3.6 million; when converted into [full-time equivalents](#) the number of R & D personnel in 2010 was 2.5 million, of whom approximately one third were women. Among the other G20 members with data available (see Table 3) China had the next largest R & D workforce (3.2 million), followed by Japan and Russia – note that the Russian head count data is an underestimate and the data in full-time equivalents shows that the R & D personnel input in Russia was close to that in Japan.

The sectoral division of R & D personnel was broadly similar to that for the analysis of the sectoral performance of R & D expenditure; the main difference was that the share of personnel in higher education institutions was generally larger than the equivalent share of R & D expenditure with the reverse situation in the business enterprise sector. Canada was a notable exception to this rule, with nearly two thirds of its R & D personnel in the business enterprise sector that was responsible for about half of its R & D expenditure.

Table 4 provides a similar analysis to that in Table 3, but focuses on the core occupation of researchers, in other words professionals engaged in the conception or creation of new knowledge, products, processes, methods and systems; persons involved in project management are also included. The number of researchers in 2009 in the EU27 was around 2.3 million or 1.6 million (2010 data) in terms of full-time equivalents. The number of researchers in the United States (also in full-time equivalents) was about 10% below that in the EU27, while in China the number was around 25% lower.

Combining the information in Tables 3 and 4 it can be seen that about half the R & D personnel in China were researchers, a share that reached three quarters in Japan and four fifths in South Korea and Turkey; in the EU27 the share was 63%. Generally the share of researchers that were in higher education institutions was higher than the equivalent share for all R & D personnel – notable examples include South Africa, Australia and Mexico – while South Korea, Brazil and Japan were the only exceptions.

Patents

Japan's share of patent applications between 2000 and 2010 remained at the top of the ranking by country of origin

As well as offering protection, [patents](#) result in inventions becoming public and can be seen as an important source for providing technical information. The statistics for [patent applications](#) to the [European Patent Office \(EPO\)](#) (see Figure 4) refer to applications filed in a particular year, regardless of whether the patent was granted or not. Patent applications are assigned to a country based on the inventor's place of residence. There is a high propensity to make use of patents in Japan, the United States and South Korea within their national economies and further afield. Indeed, there were more patent applications per inhabitant to the EPO made

from Japan than there were from within the EU27.

The UN's World Intellectual Property Organisation provides estimates for global patent applications and estimates that around 2 million patent applications were made in 2010, of which 62% were filed by residents. Japan's share of patent applications fell between 2000 and 2010 by 12.3 percentage points but Japan remained at the top of the ranking by country of origin with 23.3% of all patent applications worldwide. Over the same period China's share of patent applications increased by 13.6 percentage points to move to fourth place with 15.5% of all patent applications, behind the EU27 (17.6%), the United States (21.0%) and Japan, while South Korea's share also increased substantially (up 2.8 percentage points).

Data sources and availability

The statistical data were mainly extracted during June and July 2012.

EU27 and euro area data

Almost all of the indicators presented for the EU27 and EA-17 aggregates have been drawn from Eurobase, Eurostat's online database. Eurobase is updated regularly, so there may be differences between data appearing in this publication and data that is subsequently downloaded. In exceptional cases some indicators for the EU have been extracted from international sources, for example, when values are expressed in purchasing power parities. Otherwise, [European Commission](#) sources have been used, for example, data from the Market Observatory for Energy have been used for retail fuel prices in this article.

G20 countries from the rest of the world

For the 15 G20 countries that are not members of the EU, the data presented have generally been extracted from a range of international sources listed in the [Introduction](#). In a few cases the data available from these international sources have been supplemented by data for individual countries from national statistics authorities. For some of the indicators a range of international statistical sources are available, each with their own policies and practices concerning data management (for example, concerning data validation, correction of errors, estimation of missing data, and frequency of updating). In general, attempts have been made to use only one source for each indicator in order to provide a comparable analysis between the countries.

Context

Practical applications of science are integrated in almost every moment of our lives, for example in [household](#) appliances, transport and communications equipment, medicine and health equipment. Research and development (R & D) and [innovation](#) underlie such applications and are often considered as some of the primary driving forces behind economic growth and job creation.

Information society introduced

[Information and communication technology](#) is considered as critical to improving the [competitiveness](#) of European industry and, more generally, to meeting the demands of Europe's economy and society. ICT affects many aspects of everyday life, both at work and at home, and the [European Union](#)'s policies in this area range from the regulation of entire industrial sectors to the protection of an individual's privacy. The use of ICT has been one of the main drivers of change at work and in the home for more than a decade.

The policy framework for ICT is the [i2010](#) initiative, which seeks to create a 'European information society for growth and employment' by boosting efficiency throughout the European economy by means of wider use of ICT. The initiative is designed to promote an open and competitive digital economy. It aims to boost research into information and communication technologies and their application to improve social inclusion, public services and quality of life. It is a key element of the renewed [Lisbon Strategy](#) and offers a comprehensive strategy for the ICT and media sector. Indeed, at the heart of the policy is a desire to ensure that social and geographical differences are overcome, thus creating a fully inclusive digital society. The i2010 initiative has three main priorities:

- creating a Single European Information Space, which promotes an open and competitive [internal market](#) for the information society and media services;
- stimulating the information society by strengthening investment in [innovation](#) and research in ICT;
- exploiting the benefits of ICT by fostering inclusion, better public services and quality of life through the use of ICT.

Information and communication Technology will continue to be a focus of the European policy strategies as expressed in the Europe 2020 strategy for smart sustainable and inclusive growth and the Digital Agenda for Europe. The Digital Agenda sets an ambitious action plan in seven priority areas: creating a digital Single Market, interoperability, internet trust and security, fast internet access, digital skills and inclusion, investment in research and development and ICTs to tackle the challenges of climate change and ageing society. The Digital Agenda is monitored by a newly defined benchmarking framework for the years 2011 to 2015.

[Eurostat](#) information society statistics are key to monitoring these three priorities. A i2010 benchmarking framework was approved by Member States and the [European Commission](#) in 2006, which set out a comprehensive set of benchmarking indicators on internet and [broadband](#) take-up by citizens and businesses, and on the use of computers and online services.

This article presents recent statistical data on many different aspects of the **information society** in the **European Union (EU)**. Progress in the development of the information society is regarded as critical to improve the **competitiveness** of EU industry and, more generally, to meet the demands of society and the EU economy.

Information and communication technologies (ICT) affect people's everyday lives in many ways, both at work and in the home, for example when communicating or buying online. EU policies range from regulating entire

areas such as e-commerce to trying to protect an individual's privacy.

Main statistical findings

Households and individuals

During the last decade, ICT have become widely available to the general public, both in terms of accessibility as well as cost. A boundary was crossed in 2007, when a majority (55%) of households in the EU-27 had internet access. This proportion continued to increase and in 2011 reached 73%, rising by an additional 3 percentage points compared with 2010. Widespread and affordable broadband access is one of the means of promoting a knowledge-based and informed society. In all Member States broadband was by far the most common form of internet access, used by 67% of all EU-27 households in 2011, more than double the share in 2006 - see Figure 1.

The highest proportion (94%) of households with internet access in 2011 was recorded in the Netherlands (see Figure 2), while Luxembourg, Sweden and Denmark also reported that at least nine out of every ten households had internet access in 2011. The lowest rate of internet access among the Member States was recorded in Bulgaria (45%). However, there was a rapid expansion in household access to the internet in Bulgaria, as the proportion of households with access rose by 12 percentage points between 2010 and 2011. Romania was the only other Member State where fewer than half of all households had internet access.

As of the beginning of 2011, just over seven out of every ten individuals in the EU-27, aged between 16 and 74 years, used a computer, while a similar proportion used the internet. At least nine out of every ten individuals in Sweden, the Netherlands, Luxembourg and Denmark used a computer and used the internet. However, less than half of all individuals aged 16 to 74 used a computer and the internet in Bulgaria and Romania. More than half (57%) of the individuals in the EU-27 used the internet for finding information on goods or services in 2011 - see Table 1.

Among internet users, in other words, those individuals within the EU-27 using the internet in the three months before the ICT survey, more than nine out of every ten (93%) accessed the internet from home in 2011, as shown in Table 2. In comparison, less than half of this subset of the population accessed the internet at work (42%), which in turn was around double the proportion accessing the internet from a friend's, neighbour's or relative's house (24%). The large majority of internet users accessed the internet on a daily basis - see Figure 3.

The proportion of individuals who ordered goods or services over the internet for private use has risen. In 2011, 43% of individuals aged 16 to 74 stated that they had ordered at least once over the internet - an increase of 3 percentage points compared with 2010 (see Figure 4). More than two thirds of individuals in the United Kingdom, Sweden, Denmark and the Netherlands ordered goods or services over the internet, whereas the proportion was no higher than one person in five in Latvia, Portugal, Greece, Lithuania and Italy; the lowest proportions of individuals ordering goods and services over the internet were registered in Bulgaria (7%) and Romania (6%).

Figure 5 presents information relating to the use of the internet by individuals for social networking and a range of other relatively new activities such as consulting wikis, reading and posting opinions on civic or political issues, and taking part in online consultations or voting. While an average of 38% of individuals in the EU-27 aged 16 to 74 participated in social networks in 2011, there was a wide diversity in the use of these services when broken down by age group. The proportion of individuals aged 55 to 74 using social networks stood at 11%, in sharp contrast to the 80% recorded for those aged 16 to 24. This means that social networks play a vital role for maintaining social contacts among the younger age group. Overall, the youngest age group made greater use (than their elders) of all four activities presented in Figure 5.

In 2011, a majority of individuals in the EU-27 had some basic computer skills that allowed them to copy or move files or folders: this was the case for 63% of persons aged 16 to 74 and 89% of those aged 16 to 24. Less than half of the population (aged 16 to 74) used basic arithmetic formulae in spreadsheets (43%), about one third created electronic presentations (31%) and one in ten wrote computer programs (10%). The proportion of persons aged 16 to 24 with these computer skills was much higher. Two thirds of the younger generation used formulae in spreadsheets, almost six out of ten created electronic presentations, and one in five wrote computer programs.

Enterprises

One in 20 [enterprises](#) in the EU-27 (covered by the [survey on ICT usage in enterprises](#)) did not have internet access as of the beginning of 2011 (see Figure 6), while the vast majority (87%) made use of a fixed broadband connection to access the internet. There was a rapid uptake in the use of mobile broadband technologies – in part fuelled by enterprises equipping their staff with 3G USB sticks, smart phones and other mobile devices – as almost half (47%) of enterprises in the EU-27 used mobile broadband at the start of 2011; this was 20 percentage points higher than the corresponding share for January 2010. Around seven out of every ten enterprises in the EU-27 had their own website. A similar proportion of enterprises used the internet to submit completed forms electronically to public authorities.

By the start of 2011, the proportion of enterprises with internet access exceeded 90% in all Member States except Romania, Bulgaria and Hungary, while Romania and Bulgaria were the only Member States where less than half of the enterprise population had a website – see Table 4. At the start of 2011, more than three quarters of all enterprises in Finland used mobile broadband connections to access the internet – see Figure 7. This figure was considerably higher than in any other Member State, while Sweden, Austria, France, Germany and the United Kingdom were the only other countries to report that more than half of their enterprises made use of mobile broadband connections.

As of January 2011 around three quarters of all enterprises in the EU-27 made use of the internet in order to obtain forms or information from public authorities, while a slightly lower proportion (69%) returned filled in forms to public authorities over the internet; for this latter group, the most common operations included making declarations for VAT and social contributions – see Table 5.

Radio-frequency identification (RFID) is a technology that may be used for the purpose of automatic identification and tracking; it may be used for a range of objects and in a variety of situations, although some common applications include: manufacturers using tags to track the location of each product they make; transport services enterprises using tags to track their vehicles; domestic use to be able to locate vulnerable people. Figure 8 provides some details relating to the proportion of enterprises using RFID in January 2011 and shows that the principal use made of RFID among EU-27 enterprises was for person identification and access control.

In total, [e-commerce](#) accounted for around 14% of [turnover](#) among enterprises with at least ten persons employed in the EU-27, a share that ranged from 1% in Cyprus to 25% in the Czech Republic in 2010 (see Figure 9). Some 15% of enterprises in the EU-27 sold goods or services online during 2010, which was less than half the proportion of enterprises (35%) that made purchases online (see Figure 11). The percentage of enterprises selling online was highest in the accommodation sector (58%), whereas the highest proportion of enterprises making online purchases was recorded for information and communication services (60%).

Data sources and availability

Statisticians are well aware of the challenges posed by rapid technological change in areas related to the internet and other new applications of ICTs. As such, there has been a considerable degree of evolution in this area, with statistical tools being adapted to satisfy new demands for data. Indeed, statistics within this domain are reassessed on an annual basis in order to meet user needs and reflect the rapid pace of technological change.

This approach is replicated in [Eurostat](#)'s [survey on ICT usage in households and by individuals](#) and in its survey on ICT usage in enterprises. These annual surveys are used to benchmark ICT-driven developments, both by following developments for core variables over time and by looking in greater depth at other aspects at a specific point in time. While the surveys initially concentrated on access and connectivity issues, their scope has subsequently been extended to cover a variety of subjects (for example, [e-government](#) and e-commerce) and socio-economic analysis, such as regional diversity, gender specificity, age, educational differences and the individual's [employment](#) situation in the household survey, or an analysis by enterprise size (small, [medium-sized](#) and large enterprises) in the enterprise survey. The scope of the surveys with respect to different technologies is also adapted so as to cover new product groups and means of delivering communication technologies to end-users (enterprises and households).

Households and individuals

The household survey covers those households having at least one member in the age group 16 to 74 years old. Internet access of households refers to the percentage of households that have an internet access, so that anyone in the household could use the internet at home, if so desired, even simply to send an e-mail. **Internet users** are defined as all individuals aged 16-74 who had used the internet in the three months prior to the survey. Regular internet users are individuals who used the internet, on average, at least once a week in the three months prior to the survey. The reference period for this survey was the first quarter of 2011; the survey period was the second quarter in most countries. A special module on ICT skills formed part of the 2011 survey.

The technologies most commonly used to access the internet are divided between broadband and dial-up access over a normal or an ISDN telephone line. Broadband includes **digital subscriber lines (DSL)** and uses technology that transports data at high speeds. Broadband lines are defined as having a capacity higher than ISDN, meaning equal to or higher than 144 kbit/s.

A **computer** is defined as a personal computer powered by one of the major operating systems (Macintosh, Linux or Microsoft); handheld computers or palmtops (PDAs) are also included.

The ordering of goods and services by individuals refers to the twelve months prior to the survey and includes confirmed reservations for accommodation, purchasing financial investments, participation in lotteries and betting, internet auctions, as well as information services from the internet that are directly paid for. Goods and services that are obtained via the internet for free are excluded. Orders made by manually typed e-mails are also excluded.

Enterprises

The survey on ICT usage in enterprises covers enterprises that have at least ten persons employed. The activity coverage is restricted to those enterprises whose principal activity is within manufacturing, electricity, gas, steam and water supply, sewerage and waste management, construction, wholesale and retail trade, repair of motor vehicles and motorcycles, transportation and storage, accommodation and food service activities, information and communication, real estate, professional, scientific and technical activities, administrative and support activities and the repair of computers and communication equipment (as defined by **NACE Rev. 2** Sections C to N excluding Division 75 plus Group 95.1); the financial and insurance activities (Section K) are covered by the survey but are excluded from the analysis presented here.

The data collected through the enterprise survey can be analysed according to enterprise size (in terms of persons employed), with data presented for small (10-49 persons employed), medium-sized (50-249) and large (250 or more persons employed) enterprises.

ICT usage data are grouped according to the year in which the survey was conducted; most data refer to the situation in January of the reference/survey year. A special module on the use of public services formed part of the 2011 survey. Despite the generally widespread availability of eGovernment services in Europe, there are some large differences observed in the use of these services between Member States. Some of these differences may be attributed to the obligatory (or otherwise) nature of declarations. In some countries these administrative operations have become obligatory via electronic means, whereas enterprises in other Member States may continue to submit declarations (for example, VAT or social security) on paper. Even when such submissions via electronic means are obligatory, some enterprises may indicate in statistical surveys that they do not make electronic submissions as the submissions may be made by a third party (as part of an outsourced task).

Context

Broadband technologies are considered to be important when measuring access to and use of the internet, as they offer users the possibility to rapidly transfer large volumes of data and keep access lines open. The take-up of broadband is considered to be a key indicator within the domain of ICT policy-making. Widespread access to the internet via broadband is seen as essential for the development of advanced services on the internet, such as e-business, e-government or **e-learning**. Digital subscriber lines (DSL) remain the main form of delivery for broadband technology, although alternatives, such as the use of cable, satellite, fibre optics and wireless local

loops are becoming more widespread.

Until 2010 the EU policy framework for ICT was the i2010 initiative called [A European information society for growth and employment](#) (COM(2005) 229 final), which sought to boost efficiency throughout the EU economy by means of the wider use of ICT. Having undergone a mid-term review, an updated i2010 strategy was presented in April 2008, addressing key challenges for the period 2008-2010.

In May 2010 the European Commission adopted its Communication concerning [A digital agenda for Europe](#) (COM(2010) 245 final), a strategy for a flourishing digital economy by 2020. The Digital Agenda for Europe is one of the seven flagship initiatives under the [Europe 2020 strategy](#) for smart, sustainable and inclusive growth. It outlines policies and actions aimed at maximising the benefit of the digital era to all sections of society and economy. The agenda focuses on seven priority areas for action: creating a digital single market, greater interoperability, boosting internet trust and security, providing much faster internet access, encouraging investment in research and development, enhancing [digital literacy](#) skills and inclusion, and applying ICT to address challenges facing society like climate change and the ageing population.

E-commerce statistics

Data from January 2012. Most recent data: Further Eurostat information, Main tables and Database .

This article focuses on the electronic commerce(e-commerce) statistics in the European Union (EU) and is based on the results of the 2011 Community survey on 'ICT usage and e-commerce in enterprises' . E-commerce refers here to the trading of goods or services over computer networks such as the Internet. It can be divided into e-commerce sales and e-commerce purchases according to the way in which an enterprise receives or places orders respectively.

Essentially, e-commerce is part of the business model of enterprises, complementing their conventional commercial activities for selling and buying aimed at enhancing their performance.

Note: 2008 data without enterprises in the NACE Rev 2 group 95.1 referring to 'Repair of computers and communication equipment'

Figure 1: E-commerce sales and purchases, turnover from e-commerce, 2008 to 2010, EU-27 (% of enterprises, % total turnover) Source: Eurostat (isoc_bde15dec) and (isoc_ec_evaln2)

Main statistical findings

	Enterprises with e-purchases			Enterprises with e-sales			Enterprises' turnover from e-commerce		
	2008	2009	2010	2008	2009	2010	2008	2009	2010
all enterprises	33%	37%	35%	13%	15%	15%	12%	14%	14%
large	50%	55%	56%	32%	35%	37%	17%	19%	19%
medium	40%	44%	43%	19%	22%	23%	10%	11%	10%
small	31%	35%	33%	11%	13%	13%	4%	5%	4%

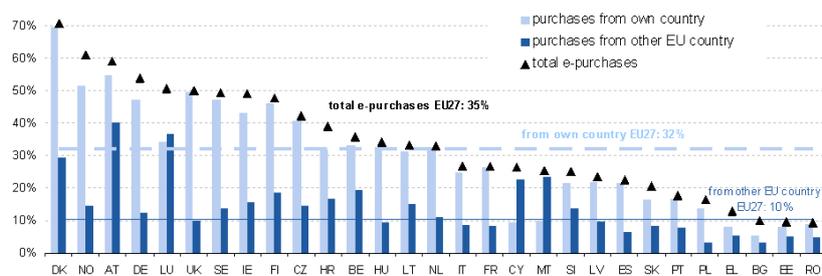

Figure 9: E-commerce purchases from own country and from other EU countries, 2010 (% of enterprises) Source: Eurostat (isoc_bde15dec)

Share of turnover from e-commerce stable at 14% in 2009 and 2010

In 2010, more than twice as many enterprises engaged in e-commerce purchases than in e-commerce sales. As shown in Figure 1, during 2010, 35% of enterprises in the EU-27 made purchases electronically, – e-purchases. In the same period, only 15% of enterprises made electronic sales – e-sales.

The percentage of turnover on e-sales amounted to 14% of the total turnover of enterprises with 10 or more persons employed in the EU-27.

However, as Table 1 shows, there was a significant variation in the share of enterprises conducting e-sales and the turnover from the e-sales according to enterprise size.

During 2010, 37% of large enterprises made e-sales corresponding to 19% of total turnover in this size class. Similarly, 23% of medium sized enterprises made e-sales corresponding to 10% of total turnover in this size class. By contrast, 13% of small enterprises engaged in e-sales, corresponding to only 4% of the turnover of such enterprises.

In the EU-27, during the period 2008 to 2010 there was a small increase in the percentage of enterprises that had purchases or sales electronically (both +2 percentage points), and also in the percentage of turnover on e-commerce sales (+2 percentage points). Changes were more noticeable depending on the size of enterprises.

Wide variation in the share of e-commerce sales and purchases among countries

In 2010, among all countries (Figure 2), the percentage of enterprises making purchases electronically varied widely from country to country, ranging from 9% in Romania to 71% in Denmark. Similarly, the percentage of enterprises with e-sales ranged from 4% in Romania to 36% in Norway, followed by Denmark (28%), Belgium and the Czech Republic (both 27%).

The bubble chart in Figure 3 shows three main clusters of countries in terms of the percentage of turnover from e-commerce in the total turnover (the bigger the bubble, the greater the share and the darker the shade). The position of the countries in Figure 3 is determined by the percentage of enterprises making e-sales (the further up in the graph, the greater the proportion of enterprises with e-sales), and the percentage of enterprises conducting e-purchases (the further to the right in the graph, the greater the proportion of enterprises with e-purchases).

During 2010, among all countries, the percentage of turnover realised from e-commerce ranged from 1% in Cyprus to 25% in the Czech Republic, followed by Finland (20%), Sweden and Hungary (both 19%).

As shown in Figure 3, in nine out of the 29 countries (EU-27, Norway and Croatia) enterprises realised more than 15% of their total turnover from e-commerce sales during 2010 (bubbles with the darkest shade). However, within this group of countries, there was a significant variation in the percentage of enterprises selling electronically, ranging from 12% in Hungary to 36% in Norway.

Similarly, regarding the percentage of enterprises purchasing electronically, the proportions within the same group of nine countries ranged from 21% in Slovakia to 61% in Norway.

Enterprises using the web dominated in the area of e-sales

Specific methods for e-commerce sales enable the “sales process” to take place in a faster and more efficient manner. These methods can be broadly divided into web sales and **EDI-type sales** referring to the way customers – private or business – place orders for the products that they wish to purchase.

Therefore, for the survey on 'ICT usage and e-commerce in enterprises', respondents were asked to state whether they received orders via a website (web sales) or in a format that allowed automated processing (EDI-type sales) using Electronic Data Interchange or Extensible Markup Language (XML) format for example.

Enterprises consider it important to be visible on the Internet. Consequently, websites are increasingly offered by enterprises or third parties for various purposes. In particular, websites allow customers to purchase by placing their orders electronically.

As shown in Figure 4, during 2010, 78% of enterprises selling electronically in the EU-27 used a website, while 35% used EDI-type sales. On the one hand, during 2010, the percentage of enterprises that used EDI-type sales ranged from 17% of enterprises conducting e-sales in Greece to 68% in the Czech Republic.

On the other hand, the percentage of enterprises receiving orders over websites was considerably high for almost all countries, ranging from 64% in Czech Republic to 92% in Malta. Only in the Czech Republic, among enterprises with e-sales, was the percentage of enterprises that reported EDI-type sales higher than those that reported web sales.

As shown in Figure 5, during 2010, almost all enterprises making e-sales in the 'Travel agency, tour operator reservation service and related activities' branch received orders via a website, while 17% made e-sales via EDI-type messages.

More than half of 'Manufacturing' enterprises making e-sales reported that they received orders via EDI-type messages, followed closely by enterprises in the 'Transport and storage' sector (46%).

The percentages for 'Manufacturing' enterprises that conducted e-sales via a website and via EDI-type messages were very close: 58% and 56% respectively. For all other economic activities, enterprises received their orders in most cases via websites.

It is noticeable that, among the small enterprises making e-sales, 83% of enterprises tended to have web sales, whereas among the large enterprises 58% received orders via websites.

The share of turnover from EDI-type sales is greater than that from web sales

In the EU-27, enterprises realised 14% of their total turnover from e-commerce during 2010, consisting of orders via a website or via EDI-type messages.

However, the turnover realised from EDI-type sales was 10% of total turnover, while the turnover from web sales was only 4%.

As Figure 5 shows, large enterprises – with 250 or more persons employed – rely in principle on ICT standards that integrate EDI-type sales within their business processes.

Figure 6 shows the cumulative contribution of web sales and EDI-type sales to total turnover. In particular, the share of the total turnover realised from EDI-type sales ranged from less than 1% in Cyprus to 19% in the Czech Republic. In addition, the share of total turnover from web sales ranged from 1% in Cyprus to just 9% in Norway.

Figure 7 shows the distribution of e-commerce turnover between web sales and EDI-type sales. In 2010, for the vast majority of countries, the share of e-commerce turnover from EDI-type sales was greater than the share from sales via websites, except for Lithuania, Latvia, Greece, Bulgaria and Cyprus. In particular, for enterprises

making e-sales in Slovakia, the percentage of turnover realised by EDI-type sales was almost six times that from web sales.

Cross border e-commerce sales not fully exploited by enterprises selling electronically

E-commerce enables enterprises to establish their presence in the market at national level and also to extend their economic activities beyond national borders in order to pursue opportunities elsewhere. Moreover, e-commerce has the potential to reshape the European Single Market for enterprises and private consumers by enabling price and product-related comparisons in a borderless market environment.

However, in 2010 in the EU-27, while almost all enterprises making electronic sales (15%) reported that they sold to the markets in their own countries (14%), only 6% of enterprises made e-sales to other EU countries (Figure 8).

In particular, the potential for cross-border e-commerce sales to other EU countries was not fully exploited. While 28% of enterprises in Denmark made e-sales — ranking it first among the EU countries — only 8% of enterprises reported selling to customers in other EU countries. A similar phenomenon can be observed for Sweden, where 26% of enterprises made e-sales but only 9% sold to other EU countries.

Outside the EU, Norway has the highest potential for enterprises to expand into foreign markets, with 36% of enterprises making e-sales but only 7% to customers in EU countries.

Concerning e-purchases (Figure 9), in 2010 in the EU-27, while almost all enterprises making electronic purchases (35%) reported purchasing from their domestic markets (32%), only 10% of enterprises made e-purchases from other EU countries.

In 2010, the biggest differences between the percentages of enterprises making e-purchases in general and those purchasing electronically from other EU countries can be observed in Norway and Germany. In Norway, 61% of enterprises made e-purchases, while 15% purchased electronically from suppliers in an EU country. Similarly, in Germany 5 out of 10 enterprises made e-purchases, while only 1 in 10 made e-purchases from another EU country.

Across all countries, the highest percentage of e-purchases from other EU countries was reported in Austria.

In Luxembourg, Malta and Cyprus, more enterprises reported e-purchases from other EU countries, because the relatively small local markets were not sufficient to meet demand.

Data sources and availability

In 2011, 146000 enterprises, with 10 or more persons employed, out of 1.5 million in EU-27 were surveyed. Out of these 1.5 million enterprises approximately 83% were enterprises with 10-49 persons employed, 14% with 50-249 and 3% with 250 or more.

Data in some tables are shown as "-" and refer to not available, unreliable, confidential or not applicable. Unreliable data are included in the calculation of European aggregates.

IS: no survey in 2011.

Figure 6 and Figure 7: only countries that have reported turnover for both, web sales and EDI-type sales, are presented in the graphs.

Context

Data presented in this article are based on the results of the 2011 Community survey on 'ICT usage and e-commerce in enterprises'. Statistics were obtained from enterprise surveys conducted by National Statistical Authorities in 2011. The surveys' reference period was January 2011 or for some questions (like e.g. e-commerce)

the year 2010.

The observation statistical unit is the enterprise, as defined in the [Regulation 696/1993](#) of 15 March 1993. The survey covered enterprises with at least 10 persons employed. Economic activities correspond to the classification [NACE](#) Revision 2. The sectors covered are manufacturing, electricity, gas and steam, water supply, construction, wholesale and retail trades, repair of motor vehicles and motorcycles, transportation and storage, accommodation and food service activities, information and communication, real estate, professional, scientific and technical activities, administrative and support activities and repair of computers and communication equipment. Enterprises are broken down by size; small (10-49), medium (50-249) and large enterprises (250 or more persons employed).

E-government statistics

Data from May 2010, most recent data: Further Eurostat information, Main tables and Database .

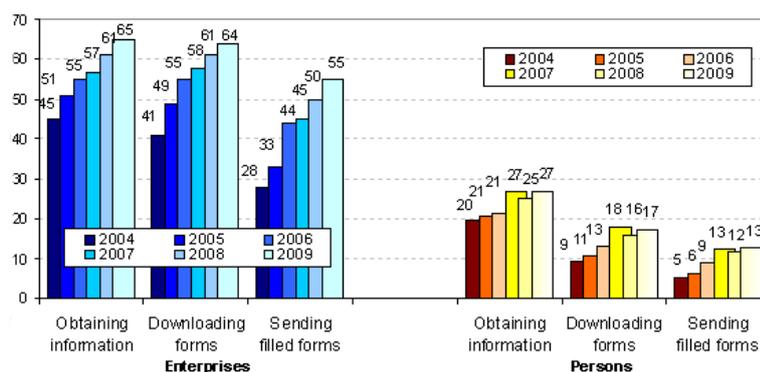

Online interactions of European businesses and citizens with public administrations

This article highlights the development and use of [information and communication technology \(ICT\)](#) for interacting with public administrations in the [European Union \(EU\)](#) . This is one aspect of [e-government](#) , which is designed to improve public services and democratic processes by means of the Internet. Inclusion and better public services are part of the third priority of the [European Commission i2010 initiative](#) .

Main statistical findings

- The types of electronic interaction with public administrations are, in order of popularity:
 1. obtaining information
 2. downloading forms
 3. returning completed forms electronically
 4. managing administrative procedures completely electronically
- In the EU, there is a steady increase in the proportion of both individuals and businesses that interact with public authorities via the Internet.
- From 2004 to 2009, the proportion of [enterprises](#) (businesses and companies) which were interacting with public bodies over the Internet was higher, and growing at a faster rate, than the proportion of individuals.
- Lithuania has the highest proportion of companies that return completed forms over the Internet and, between 2004 and 2009, Lithuania progressed the most in returning such forms.
- A higher percentage of [large enterprises](#) (as compared to [medium-sized](#) and [small ones](#)) interact online with public authorities.
- After a steady increase from 2004 to 2007, the share of citizens interacting with public authorities has stagnated since 2007 in the EU overall.
- More than one third of Internet users in 2006 have already profited from e-government services and another 37% would be interested in doing so.
- [Educational levels](#) influence the actual use of e-government services as well as the interest in using them.
- Lack of personal contact is the most frequent reason for not using e-government services.
- There is a relationship between the types of e-government services requested and a citizen's profile based on age, professional and social status.

Development of e-government services usage

Graph 1: Online interaction of enterprises during reference year and of individuals during last 3 months with public authorities in EU-27, 2004 - 2009[1]

The most frequent type of interaction with public administrations over the Internet is to obtain information, followed by downloading official forms. The least frequent (of the three interaction types) is the returning of completed forms. In 2006, figures for the downloading of official forms by enterprises reached the same level as those for obtaining information. In 2009, 65% of European enterprises downloaded official forms, as compared to 17% of individuals. The discrepancy is even higher for returning completed forms. A higher percentage of enterprises interact with public administrations than do individuals. This can be partly explained by the disparities in their Internet access and connections. In 2009, 93% of businesses, as compared to 65% of households, had Internet connections. Furthermore, businesses are likely to have more interactions with public authorities than individuals anyway. And these business interactions offer a high potential for automating processes - which can increase business efficiency. However, the actual level of such interactions is also determined by the online availability of the public administration. Finally, the reference period for enterprises was one year while it was three months for individuals.

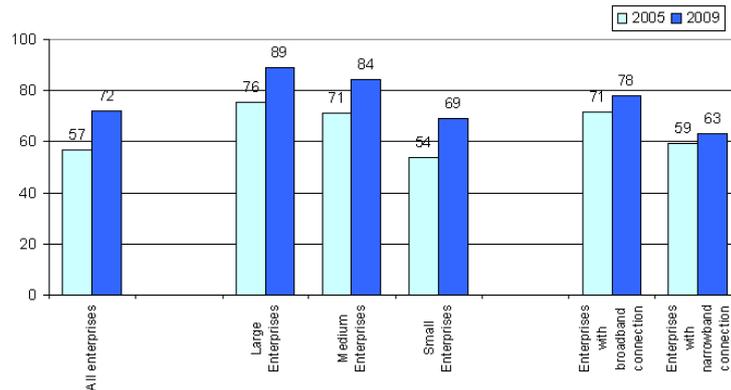

In 2005, the biggest increase for both enterprises and individuals was in the downloading of forms, whereas in 2006, the interaction "returning completed forms" showed the highest growth rates. This latter type of interaction is very interesting for cost savings, as it has the potential to become fully automated. From the public administration side, receiving completed forms online represents a first step towards a fully electronic case-handling process. In 2007, all three types of interactions increased considerably for individuals, whereas the growth rate for enterprises was lagging behind. From 2008 onwards, we observe a stagnation for electronic interactions between citizens and public administrations, whereas the share of enterprises increases again.

E-government services and enterprises

In 2009, almost two thirds (65%) of EU enterprises either obtained information or downloaded official forms from public authorities' websites. More than half (55%) of these enterprises then returned the completed forms to public administrations. 44% of the enterprises treated administrative procedures completely electronically, i.e. without the need for exchanging information in paper form. Around one tenth (11%) of the enterprises submitted a proposal using an electronic tendering system.

	Obtaining information	Downloading forms	Sending filled forms	Treating administrative procedure completely electronically	Submitting a proposal in an electronic tender system
All enterprises	65	64	55	44	11
Large enterprises	85	84	79	63	21
Medium-sized enterprises	78	79	72	57	16
Small enterprises	62	61	51	41	10
Enterprises with broadband connection	70	70	60	48	12
Enterprises with narrowband connection	55	55	44	31	9

Table 1: Online interaction of enterprises with public authorities, 2009

Graph 2: Any online interaction of enterprises with public authorities by size class and type of Internet connection in EU, 2005-2009

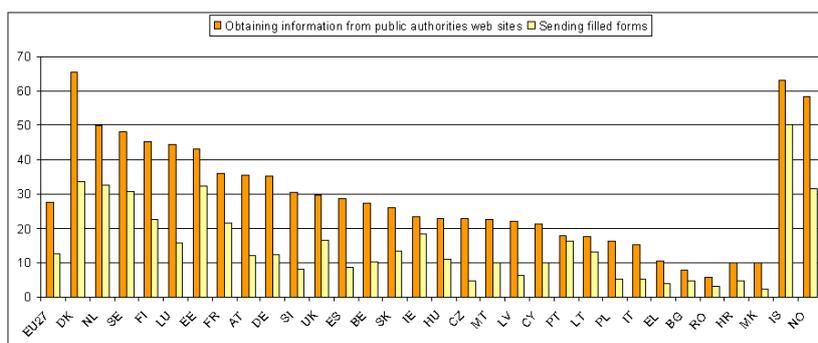

The volume of interaction between businesses and public administrations varies with the Internet connection bandwidth and the size of the enterprise. A higher percentage of enterprises with **broadband**, compared to **narrowband** connections, interact with public authorities. However, the largest divergence between enterprises is due to their size. 89% of large enterprises and 84% of medium-sized enterprises interact with public administrations online as compared to only 69% of small enterprises. The increase between 2005 and 2009 was 13 percentage points for large and medium sized enterprises and 15 percentage points for small enterprises. However, considering the already reached levels in 2005, large enterprise filled more than half of the remaining gap (from 76% to full saturation at 100%) until 2009 while this increase was only one third for small enterprises (15% points out of 46% points from 2005 to 2009). Obviously, large enterprises take more advantage of the Internet for interacting with public administrations.

Between 2004 and 2009, at the European level (**EU-27**), the proportion of companies that returned completed forms via the Internet increased from 28% to 50%. From 2005 to 2006, this development had accelerated but, in 2007, progress almost came to a standstill. This was due to the results from Belgium, Spain, Italy, Austria, Poland and Finland, whereas in other Member States there had been a considerable increase, namely in Ireland, Hungary, Portugal, Slovenia and Slovakia. In 2008, at EU level, the proportion of enterprises returning forms online increased by 5%. The countries with the largest percentage of interacting companies were Finland, followed by Lithuania and the Netherlands. Considering the initial level in 2004, the highest increase can be found in the Netherlands, Lithuania, Ireland and Slovenia. Between 2004 and 2008, at the EU level, the probability that enterprises would return completed forms online to public administrations almost doubled.

E-government services and the citizens

	EU-27	BE	BG	CZ	DK	DE	EE	IE	EL	ES	FR	IT	CY	LV	LT	LU	HU	MT	NL	AT	PL	PT	RO	SI	SK	FI	SE	UK	IS	NO

Table 2: Enterprises returning completed forms online, 2004-2009 (see [list of country abbreviations](#))

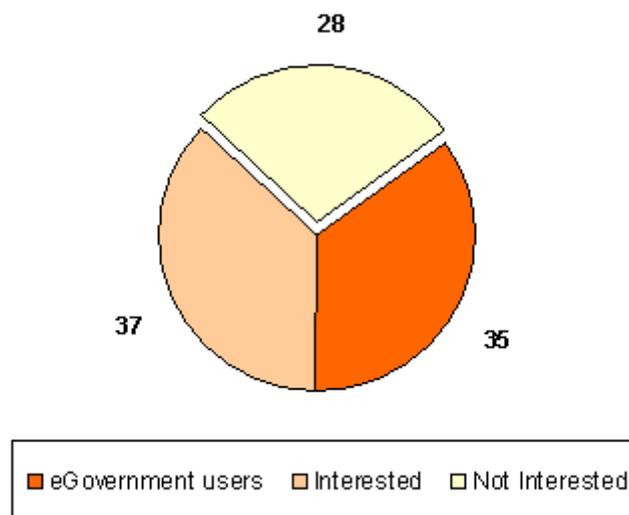

Graph 3: Online interaction of individuals with public authorities, 2009

Use of online services by the citizens On average, 28% of the European citizens accessed information on public authorities' websites in 2009. Only 13% of European citizens sent information electronically within 3 months prior to the survey in 2009. There is still a big potential for e-government services to citizens in Europe, which can be exploited in the next years. There are big differences in the percentage of use of online services between the European countries. While almost two thirds (65%) of the citizens in Denmark have already looked for information from public authorities online, only 6% of Romanian citizens have searched for information on public authorities' websites. Providing information online is the first step of sophistication of e-government initiatives. The next steps are to give the possibility to download forms from the Internet and to complete online forms and send them to public administrations online. The last step requires to introduce new business processes in public administrations requiring considerable investments from the governments. On the other hand, this bears a high potential of rationalisation for public administrations and leads to more transparent and faster procedures. Comparing the European countries, Denmark, the Netherlands, Estonia and Sweden are the leading countries where the highest percentage of citizens send electronic forms to public administrations. In the Czech Republic, Bulgaria, Greece and Romania, this percentage is below 5% in 2009.

Graph 4: Obtaining information online from public authorities websites in EU-27, 2009

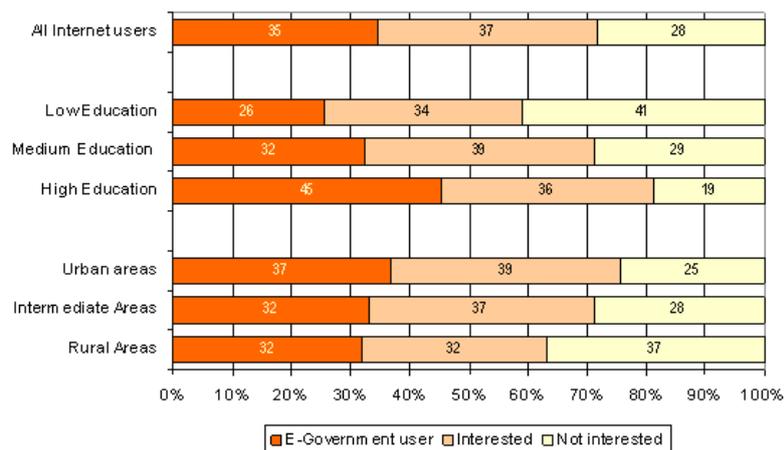

Graph 5: Replacement of personal contacts or visits to public services with the Internet in the EU, 2006

Use of online services by socio-economic groups The **digital divide** is visible in the use of e-government services, too. The share of persons interacting electronically with public authorities is remarkably different comparing different groups of the society. On average, 28% of the citizens within the EU have obtained information online from public authorities' websites in 2009. More than half (53%) of persons with higher formal education used these services compared to only 12% of persons with no or low formal education. Differences by educational attainment are the most remarkable within the data set. A higher percentage of persons living in urban areas (32%) have accessed information on public authorities' website than those living in rural areas (22%). The most significant figure related to occupation is the low percentage of retired and inactive persons having obtained information online from public authorities in 2009. This phenomenon can as well be observed for the different age classes. Starting with the age class 25 to 34 years, the percentage of persons accessing information online decreases from 39% to a minimum of 8% for the age class 65 to 74 years. Normally, the youngest age group shows the highest percentage of Internet activities among the different age groups. This is not the case for e-government activities, which can be explained by less need or fewer obligations concerning administrative procedures for younger people.

Interest in using e-government services In 2006, within the EU, more than a third (35%) of individual Internet users had already used e-government services. In addition, another 37% of them would have been interested in replacing personal visits to public authorities with services via the Internet. However, the remaining 28% of Internet users were not interested in requesting services from public authorities online. The highest percentage of Internet users who already use e-government services are found in Iceland, Denmark, the Netherlands and Estonia. The highest proportion of Internet users who are not interested in e-government services are found in Latvia, the Czech Republic, Romania and Ireland. As expected, there is a tendency for those Member States with a high percentage of e-government users to show a corresponding lower percentage of potential users.

Table 3: Replacement of personal contacts or visits to public services with Internet, 2006 (see [list of country abbreviations](#)).

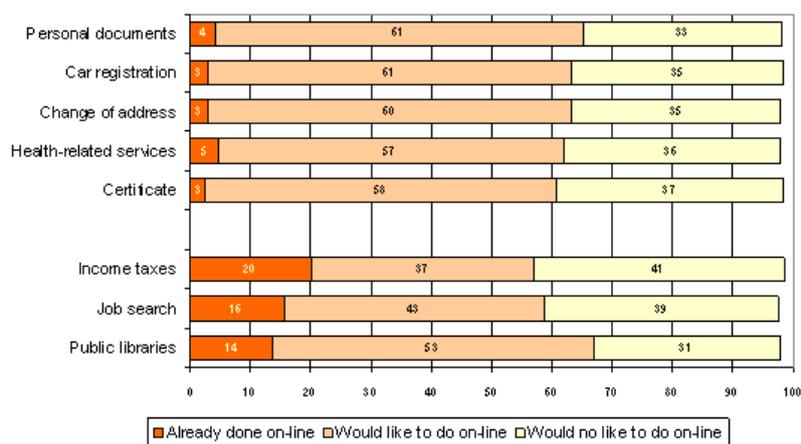

Graph 6: Replacement of personal contacts or visits to public services with Internet in EU, 2006

Education is a factor that influences the ability and willingness of individuals to replace personal visits to public authorities by e-government services. Those with a higher level of education are more likely to use e-government services, whereas the proportion of individuals who are not interested in e-government services is the highest among those with low educational backgrounds. And remarkable differences can be seen between urban, intermediate and rural areas, primarily in the percentage of Internet users who are not interested in e-government. Internet users in rural areas are less interested than those users in urban areas, although the former may benefit more from using e-government services due to the longer distances they need to travel to the authorities in rural areas, as compared to urban ones.

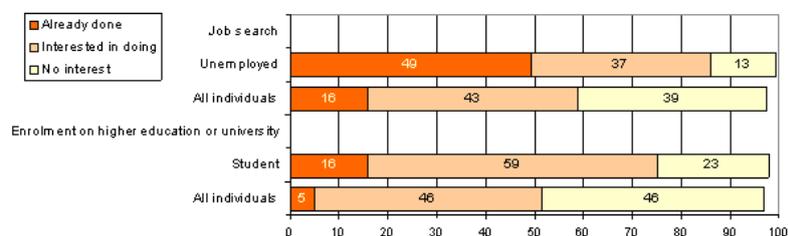

Graph 7: Reasons for abstaining from e-government services in EU, 2006[2]

Reasons for abstaining from e-government services Citizens were asked for their reasons for not using online government services. The most mentioned obstacle was the lack of personal contact followed by concerns about data protection and security. The complexity of online applications and their availability were mentioned by 15% of respondents. Moreover, 13% missed getting an immediate response. This might be closely related to the lack of face-to-face personal contacts. Only 7% of the citizens were concerned about additional costs incurred by online government services.

Graph 8: E-government participation by types of e-government services in EU, 2006[3]

Use of e-government services by type of service Interest among Internet users in having access to specific services online is dependent on the personal situation of the individual. Unemployed people want to use different services than, say, students. Nevertheless, there are some general services which are of interest to everyone between the ages of 16 and 74. The levels of usage of these general services, such as requesting personal documents, health-related services, house-moving announcements, requesting certificates and car registrations are very similar. Roughly two thirds of Internet users are interested in using or are already using them. However, the percentage of actual usage of those online services has to be considered in relation to their rather rare frequency.

Graph 9: E-government participation by types of services and population group in the EU, 2006[4]

Use of e-government services by employment situation In the EU, the declaration of income taxes, job searches and online visits to public libraries are the services with the highest percentage of users. However, in general, people's interest in declaring their income taxes and searching for jobs is lower than their interest in the other services.

Data sources and availability

The source for the data in this article are the [Community survey on ICT usage in households and by individuals](#) and the [Community survey on ICT usage in enterprises](#) .

An EU aggregate is only calculated if the available countries represent at least 55% of the number of Member States and at least 60% of the EU population. “:” refers to data which are confidential, unreliable or unavailable.

Context

In the EU, the development and use of ICTs for doing business with public administrations is one aspect of e-government which is designed to improve public services and democratic processes by means of the Internet. Inclusion and better public services are part of the third priority of the EC's i2010 initiative.

Notes

ICT security in enterprises

Data from February 2011, most recent data: Further Eurostat information, Main tables and Database .

This article analyses recent statistical data on [information and communication technologies \(ICT\)](#) security in the [European Union \(EU\)](#) . Results were obtained through a specific set of questions in the 2010 questionnaire of the [Community survey on ICT usage and e-commerce in enterprises](#) . In this context, ICT security refers to relevant incidents as well as measures, controls and procedures applied by [enterprises](#) in order to ensure integrity, confidentiality and availability of their data and ICT systems.

Table 5: Enterprises with a formally defined ICT security policy with a plan for regular review addressing specific security risks, January 2010 (% of enterprises) Eurostat (isoc_cisce_ra)

Column	ICT security policy and relevant risks addressed (Table 5)
(1)	Enterprises that had a formally defined ICT security policy
(2)	Destruction or corruption of data due to an attack or by unexpected incident
(3)	Disclosure of confidential data due to intrusion, pharming, phishing attacks
(4)	Unavailability of ICT services due to an attack from outside
(5)	Addressed all risks; (2), (3) and (4)

ICT security policy and relevant risks addressed (Table 5).PNG

Main statistical findings

In January 2010, 27% of enterprises in the EU-27 had a formally defined ICT security policy with a plan for regular review; the corresponding shares in Sweden, Norway and Denmark were over 40%.

The highest percentage of enterprises with a formally defined ICT security policy addressing the risks of destruction or corruption of data due to an attack or some other unexpected incident was reported in Norway (42%).

Voluntary training or use of generally available information was the approach most commonly reported by enterprises for making their staff aware of their obligations in relation to ICT security. The highest proportions of enterprises which have adopted this approach were registered in Cyprus and Finland with 77% and 74% respectively.

In the majority of EU-27 Member States, the disclosure of confidential data due to intrusion, pharming or phishing attacks was reported by 1% or less of enterprises in 2009.

In January 2010, the use of strong password authentication was the most commonly reported procedure used by enterprises for internal ICT security, with the highest share registered in Italy (64%).

By enterprise size, sector and country

The share of large enterprises that had a formally defined ICT security policy was three times more than the share of small ones.

The existence of an ICT security policy in an enterprise means that the enterprise is aware of the importance of its ICT and the related risks. The survey focus was on policies which were actually applied, hence regularly reviewed and accordingly adapted. In January 2010, almost three out of ten enterprises in the EU-27 had a formally defined ICT security policy with a plan for regular review.

Figure 1 shows that the share of large enterprises that had a formally defined ICT security policy was three times more than the share of small ones. The highest proportion of enterprises having such a policy (52%) in the EU-27 was reported within the sector Information and communication activities (Figure 2). The lowest proportions — less than one out of four enterprises — were registered in the sectors Transportation and storage, Construction and Accommodation and Food service activities.

As Figure 3 shows, in January 2010, the highest proportions of enterprises having a formally defined ICT security policy with a plan for regular review were registered in Sweden and Norway (both 46%) followed by Denmark (43%). In more than half of the countries, Information and communication activities had the highest percentages of enterprises with an ICT security policy. The lowest percentage for enterprises with such a policy was reported in Accommodation and Food service activities in a majority of the countries. Less than 10% of the enterprises in Romania, Hungary and Bulgaria reported that they had a formally defined ICT security policy. It should be noted that unreliable data for specific economic activities (highest/lowest) are not shown in Figure 3 but are included in the totals (EU-27 and All economic activities aggregates) of Figures 2 and 3.

Types of risks

The risk of destruction or corruption of data due to an attack or some other unexpected incident is the risk mostly addressed by enterprises' ICT security policies.

The three types of risks addressed by enterprises having a formally defined ICT security policy with a plan for regular review correspond essentially to the core elements of the ICT security definition, i.e. integrity, confidentiality and availability of data and systems.

Three types of risks that an enterprise's ICT security policy addresses:
Type 1: Destruction or corruption of data due to an attack or some other unexpected incident
Type 2: Disclosure of confidential data due to intrusion, pharming, phishing attacks
Type 3: Unavailability of ICT services due to an attack from outside

In January 2010, the highest percentage of enterprises which addressed the Type 1 risk was reported in Norway (42%), followed by Denmark, Greece and Sweden with 38% respectively.

Similarly, 37% of enterprises in Norway had a formally defined ICT security policy which addressed the Type 2 risk, followed by Sweden and Slovakia with 35% and 34% respectively.

Slovakia reported the highest percentage of enterprises (35%) which addressed the risk of unavailability of ICT services due to an attack from outside (Type 3).

Additionally, as Figure 4 shows, Slovakia reported the highest percentage of enterprises (34%) having a formally defined ICT security policy which addressed all three types of risks, followed by Norway and Denmark with 30% and 29% respectively.

Approaches to risks

Voluntary training or use of generally available information was the approach reported by most of the enterprises to make staff aware of their ICT-related security obligations.

Enterprises adopt various approaches aiming at raising awareness of ICT security policy and the relevant risks. The three approaches adopted by enterprises differ in their obligatory character and the legally binding obligations for the staff concerned.

Three approaches for raising awareness of staff's obligations in relation to ICT security:

Approach 1: Compulsory training or presentations

Approach 2: Contracts, e.g. contract of employment

Approach 3: Voluntary training or generally available information (intranet, news letters, paper documents)

In January 2010, the approach most commonly reported by enterprises for making their staff aware of their obligations in relation to ICT security was voluntary training or generally available information (approach 3).

As Figure 5 shows, the highest proportions of enterprises adopting this approach were registered in Cyprus and Finland with 77% and 74% respectively.

The second favourite approach reported by enterprises for making staff aware of their obligations in relation to ICT security was through contractual agreements e.g. contracts of employment (approach 2). The share of enterprises reporting this approach was highest in Norway and Ireland with more than 4 out of 10 enterprises.

Italy reported the highest percentage of enterprises (39%) which adopted compulsory training or presentations (approach 1) followed by Norway and Slovakia with 37% and 33% respectively.

Almost two thirds of EU-Member States reported a higher percentage of enterprises having used at least one of the approaches than the EU-27 average (48%). Moreover, Cyprus (84%) and Finland (80%) reported the highest proportions of enterprises that have adopted at least one of the three specific approaches.

Figure 6 shows that approaches 3 and 2 are most commonly adopted by enterprises in the EU-27 in the sector Information and communication (58% and 51% respectively) followed by those in Professional and scientific activities (48% and 42% respectively).

Compulsory training and presentations (approach 1) was recorded mostly by enterprises in Repair of computers and communication equipment (39%) and in Information and communication (35%) activities.

Security incidents

In 2009, three out of 20 enterprises experienced an ICT-related security incident

ICT-related security incidents concern the core elements of information security, integrity, confidentiality and availability of the data and the IT systems.

There are four types of ICT security-related incidents that result in:

Type 1: Unavailability of ICT services, destruction or corruption of data due to hardware or software failures

Type 2: Unavailability of ICT services due to attacks from outside e.g. denial of service attack

Type 3: Destruction or corruption of data due to infection or malicious software or unauthorised access

Type 4: Disclosure of confidential data due to intrusion, pharming, phishing attacks

In 2009, as Figure 7 shows, the incidents most commonly reported by enterprises were those resulting in unavailability of ICT services, destruction or corruption of data due to hardware or software failures (type 1), with shares above 20% registered in Cyprus, Portugal and Finland (26% of enterprises respectively), Denmark (24%), Greece (23%), the Czech Republic (22%) and Slovakia (20%).

In 2009, the highest proportion of enterprises reporting ICT incidents resulting in the destruction or corruption of data due to malicious software infection or unauthorised access (type 3) was registered in Slovakia (16%), Portugal (14%), Spain (11%) and Greece (10%).

The share of enterprises reporting unavailability of ICT services due to an attack from outside (type 2) was highest in Slovakia (11%) and the Netherlands (7%). In the majority of EU Member States, the disclosure of confidential data due to intrusion, pharming or phishing attacks was reported by 1% or less of enterprises in 2009.

Internal security procedures

Offsite data backup and strong password authentication were the most common internal security procedures applied.

Identification refers to the ability to identify and distinguish between individual users. User identification is considered as common practice in enterprises and usually complemented by authentication procedures. In general, identification and authentication of users are part of the authorisation process. Authorisation defines access and usage rights related to specific information or services.

In January 2010, strong password authentication was the most commonly reported procedure used for internal ICT security, with the highest shares registered in Italy (64%), Ireland (63%) and Spain (61%).

As Figure 8 shows, among all countries, the highest proportions of enterprises reporting the use of hardware tokens for user identification and authentication were registered in Croatia (49%) and Slovenia (48%).

At the same time, Italy (66%), Ireland and Slovenia (both 64%) reported the highest proportions of enterprises that had used at least one of these internal ICT security facilities.

Offsite data backup is part of the data protection strategy of sending critical data from the main site to another location by means of removable storage media, e.g. magnetic type, external hard-disks, or electronically via remote backup services.

As Figure 9 shows, the highest proportions of enterprises using offsite backup among all countries were registered in Denmark and Norway (both 76%) followed by Sweden (69%) and Iceland (73%).

One out of four enterprises in the EU-27 had used logging activities for analyses of security incidents, with the highest proportions of enterprises registered in Finland, Norway (both 47%), Sweden (42%) and Belgium (40%).

Data sources and availability

Source

Data presented in this publication are based on the results of the 2010 Community survey on 'ICT usage and eCommerce in enterprises'. Statistics were obtained from enterprise surveys conducted by national statistical authorities in 2010. The surveys' reference period was January 2010 or for some questions the year 2009.

Sample size

In 2010, 149900 enterprises out of 1.6 million in the EU-27 were surveyed.

Symbols

Data in some tables are shown as ":" and refer to not available, unreliable or confidential. Unreliable data are included in the calculation of European aggregates.

Main concepts: The observation statistical unit is the enterprise, as defined in the [Regulation 696/1993](#) of 15 March 1993. The survey covered enterprises with at least 10 persons employed.

Economic activities correspond to the classification [NACE](#) Revision 2. The sectors covered are manufacturing, electricity, gas and steam, water supply, construction, wholesale and retail trades, repair of motor vehicles and motorcycles, transportation and storage, accommodation and food service activities, information and communication, real estate, professional, scientific and technical activities, administrative and support activities and repair of computers and communication equipment. Enterprises are broken down by size: small (10-49), medium (50-249) and large enterprises (250 or more persons employed).

ICT-related security incidents affect the ICT system of an enterprise and may cause different problems. The following security incidents were covered in the survey:

- Unavailability of ICT services, destruction or corruption of data due to hardware or software failures refers to issues of data integrity caused by hardware or software failures, e.g. crashes of servers or hard disks due to hardware failures or crashes of servers due to software failures, e.g. erroneous updates.
- Unavailability of ICT services due to attack from outside refers to attempts from outside to make an information system resource unavailable to its intended users. One aim of these attacks is to prevent an internet site or service from functioning efficiently, e.g. websites of banks, credit card payment gateways.
- Destruction or corruption of data due to malicious software infection or unauthorised access.
- Disclosure of confidential data due to intrusion, pharming, phishing attacks refers to an attempt to get confidential information on persons, staff or clients, intellectual property or other confidential information. Intrusion is an attempt to bypass security controls on an information system by viruses, worms, Trojan horses etc. Phishing is a criminally fraudulent attempt to acquire sensitive information such as usernames, passwords and credit card details by masquerading as a trustworthy entity in an electronic communication. Pharming is an attack which redirects the traffic of a website to another, bogus website in order to acquire sensitive information.

User identification refers to the ability to identify and distinguish between individual users.

Authentication means to assure the identity of a certain user. Authentication and identification of users are applied in the context of authorisation, to define access and usage rights related to specific information or services. Authentication can be done with the help of passwords, or with additional devices, such as smart cards, hardware tokens or identity cards. Strong password authentication means a minimum length of 8 mixed characters, a maximum duration of 6 months, encrypted transmission and storage. A hardware token is a physical device that authorises the access of the owner of the token to a computer or a network. Hardware tokens provide an extra level of assurance in addition to the personal identification number (PIN), which authorises users as the owner of that particular device; the device generates a number which uniquely identifies the user to the service, and allows logging in. Additionally, an enterprise's ICT security information system may include the logging of applications or user activities. The logs can be used for analysis in case of security incidents in order to take appropriate action to prevent these kinds of incidents in future or to quantify any damage. Intrusion detection is a process with the purpose of detecting intrusions or attempts of intrusion into a computer or network to compromise confidentiality, integrity or availability by observation of system, application and user activity as well as network traffic.

Context

Information and communication technologies (ICT) have been one of the main drivers of changes within European Union society and businesses for more than a decade. Statistics on the resulting 'information society' monitor three aspects:

- the completion of a single European information space
- innovation and investment in ICT research;
- achieving an inclusive European information society.

These aspects correspond with the main aims of i2010 – a European Information Society for growth and employment. This is a strategic framework for the information society and a key element of the renewed [Lisbon Strategy](#) , and it offers a comprehensive strategy for the ICT and media sector.

Information society statistics at regional level

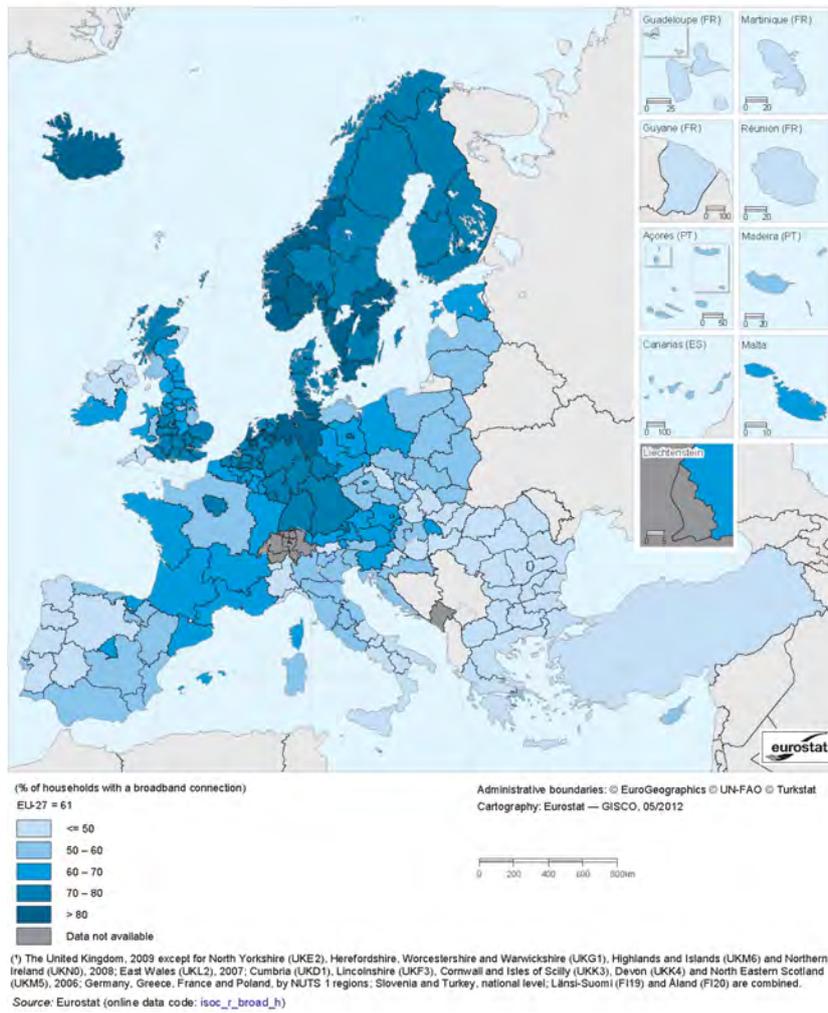

Data from February 2012. Most recent data: Further Eurostat information, Main tables and Database .

This article gives an overview of recent statistical data on access to [information and communication technology \(ICT\)](#) at regional level in the [European Union \(EU\)](#) .

The widespread use of the Internet and the World Wide Web has led the development of what is often referred to as the information society. These related developments have created new dimensions of economic, social and political participation for individuals and groups. Online activities have become ubiquitous, meaning that the actual geographic location where they are performed usually does not matter, as long as there is a connection to the Internet.

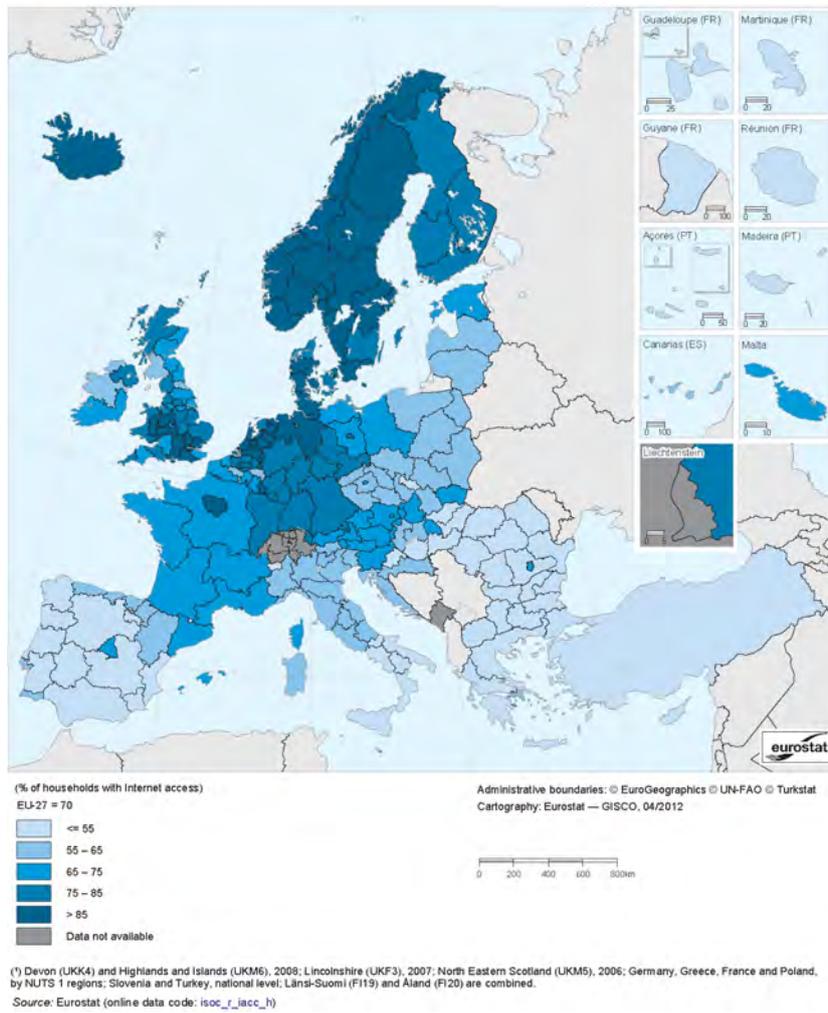

The term [digital divide](#) has been coined to distinguish between those who have [access to the Internet](#) and are able to make use of the services offered on the World Wide Web and those who are excluded from these developments. This article emphasises the geographic aspects of the digital divide within the EU.

Table 1: Top 10 EU-27 regions in terms of increasing use of the Internet, 2008-2010 (1) - Source: Eurostat (isoc_r_broad_h), (isoc_r_iacc_h), (isoc_r_iuse) and (isoc_r_blt12_i)

Main statistical findings

The maps in this article show the level of Internet access and [usage](#), including use for online purchasing, in 2010. Regional data is available for all EU Member States, as well as Iceland, Norway, Montenegro, Croatia and the former Yugoslav Republic of Macedonia, while national data is included for Turkey.

Access to information and communication technologies

Access to [information and communication technologies \(ICT\)](#) is at the heart of the digital divide, and geographic location is just one aspect of this divide. Statistics on Internet connections and [broadband](#) access are closely related, as broadband is a type of Internet connection; efforts have been made across the EU to foster broadband Internet access. In 2011, more than seven out of ten (73%) households had access to the Internet at home and more than two thirds (68% of households) accessed the Internet via broadband. These shares have grown rapidly in recent years, with average annual growth between 2006 and 2011 of 8.3% for Internet access and 17.8% for broadband access.

Maps 1 and 2 show the take-up of Internet and broadband connections by [households](#) : this regional data is available for the 2010 reference year, when 70% of households had access to the Internet at home and 61% had a broadband connection. The regional differences in Internet access within the EU were quite large, from 26% of households in Severoiztochen and Severozapaden (both Bulgaria) to 95% or more in Flevoland and Overijssel (both in the Netherlands); in other words, a factor of 3.7 to 1. Overall there were 35 regions where more than 85% of households had Internet access, while 43 regions recorded access rates of 55% or lower — of these there were 16 regions where 45% or less of households had access. Among regions in Iceland and Norway, Internet access rates were generally very high, the lowest penetration rate being 86% in Trøndelag (Norway), while rates in [candidate countries](#) were generally below the EU-27 average, ranging from 42% of households in Turkey (no regional data available) to 61% in Središnja i Istocna (Panonska) Hrvatska (Croatia).

Growth between 2008 and 2010 in the proportion of households with Internet access was generally high in most regions of Greece, Bulgaria, Romania and the Czech Republic. Overall, 12 regions within the EU averaged increases of more than 20% per annum, as did the former Yugoslav Republic of Macedonia. In many regions Internet access rates appear to have stabilised, with 14 regions recording annual average rates of change below 2%; while six regions in the Netherlands, Austria and the United Kingdom saw their respective shares of households with Internet access stagnate between 2008 and 2010. When interpreting growth rates it should be borne in mind that it is easier to achieve high growth rates when starting from a lower level, whereas those regions approaching saturation are more likely to display a slowing down of growth rates, stagnation or even a slight reversal (a reduced proportion of households with Internet access).

The situation for broadband access was to some extent comparable with that for Internet access, although the regional differences tended to be somewhat larger in relative terms. In Stockholm (Sweden) around 87% of households had broadband connections in 2010, whereas in Sud-Vest Oltenia (Romania) the share was 15%, a factor of 5.8 to 1 between the highest and the lowest shares. There were 12 regions in the EU where more than 80% of households had broadband connections: four each in Sweden and the Netherlands, two in Germany ([NUTS](#) level 1 regions), and one each in Denmark and the United Kingdom. A total of 48 regions in the EU recorded broadband connection rates of 50% or lower — of these, there were 20 regions where 40% or less of households had connections, and 12 of these had broadband connection rates of 30% or lower. For [EFTA](#) countries data are available for Norway and Iceland: broadband connection rates were above the EU-27 average, ranging from 75% in Hedmark og Oppland (Norway) to 87% in Iceland. Broadband connection rates in candidate countries were below the EU-27 average, ranging from 34% in Turkey (no regional data available) to 55% in Središnja i Istocna (Panonska) Hrvatska (Croatia).

Within the EU, 21 of the Member States have multiple (more than one) regions at NUTS level 2. An analysis of the different levels of broadband connections between regions in the same Member State can be done using measures of dispersion. This shows that Denmark, Finland, Austria, Sweden and Poland had a relatively even level of connectivity across all of their regions, whereas Bulgaria, Romania and Greece reported a much wider range in connectivity rates between regions, mainly due to the capital city region having a much higher rate than other regions.

The regions with the highest increase in broadband connection rates between 2008 and 2010 were located in Greece (Kentriki Ellada, Voreia Ellada, Nisia Aigaiou and Kriti), Italy (Calabria, and Sardegna), Romania (Vest and Nord-Vest), as well as in the United Kingdom (Shropshire and Staffordshire), the Czech Republic (Severozápad) and Bulgaria (Severozapaden); all of these regions had average annual growth of at least 40%. Only two regions in the EU recorded a fall in their respective level of broadband connections between 2008 and 2010, they were Groningen (Netherlands) and Severoiztochen (Bulgaria).

Regular use of the Internet

Over 70% of individuals in the EU-27 used the Internet in 2011 and more than two thirds (68%) were regular Internet users, in other words, they used the Internet at least once a week; the latter share rose from around 45% in 2006. There is a relation between regular use of the Internet and broadband connectivity: regions with a higher share of broadband connections can be expected to have a higher share of regular Internet users — see Map 3 which presents regional data for 2010 when an average of 65% of individuals used the Internet on a regular basis.

One of the aims of the [Digital Agenda for Europe](#) is to increase the regular use of the Internet to 75% of the total population by 2015. This indicator ranged among the EU regions from 94% of individuals in Flevoland (Netherlands) to 28% in Sud-Vest Oltenia (Romania); in other words, a factor of 3.4 to 1 which was relatively

close to the range observed for Internet access.

Overall there were 70 regions in the EU where more than 75% of individuals were regular users of the Internet, among which there were 24 regions where more than 85% of individuals were regular users. In contrast, there were 62 regions where 55% or fewer individuals were regular users of the Internet, among which were 27 regions (in Bulgaria, Greece, Italy, Portugal and Romania) where 45% or fewer individuals were regular Internet users. Among regions within EFTA countries, regular Internet use was widespread: the region with the lowest share was Sør-Østlandet (Norway) where an 86% share was 21 percentage points above the EU-27 average. The incidence of regular Internet use in candidate country regions was consistently below the EU-27 average, ranging from 33% of individuals in Turkey (no regional data available) to 57% in Središnja i Istocna (Panonska) Hrvatska (Croatia).

Measures of regional dispersion (at NUTS level 2) indicate that the incidence of regular Internet use in Finland, Slovakia and Sweden was relatively evenly spread across regions, whereas in Romania, Greece (NUTS level 1 data) and Bulgaria there was a less regular regional pattern again due to large differences between capital city regions and other regions.

E-commerce by individuals

In 2011, 43% of individuals in the EU-27 reported that they had made online purchases (within the 12 months prior to the survey date); this figure had grown from 40% in 2010 and from 26% in 2006. In 2010 the proportion of individuals making online purchases ranged across EU regions from 81% in Cumbria (United Kingdom) to 2% in the Nord-Vest and Sud – Muntenia regions of Romania and Yuzhen tsentralen in Bulgaria.

There were 87 regions where more than 50% of individuals made online purchases, among which there were 31 regions where more than 65% of individuals made online purchases, the majority (20 regions) of which were in the United Kingdom, with several in the Netherlands, Denmark and Sweden, as well as one (NUTS level 1 region) in France. In contrast, there were 35 regions where 15% or fewer of individuals made online purchases — these were mainly in Italy (nine regions), Romania (eight regions), Bulgaria (six regions) and Portugal (five regions), Greece (three NUTS level 1 regions), Hungary (three regions) and Lithuania (which is just one region).

Online purchases were relatively widespread in Norway, as the lowest regional share of online purchasing was 63% in Hedmark og Oppland, but this activity was notably less common (45%) in Iceland. People in candidate countries were less likely to have made online purchases, with only 4% having done so in the former Yugoslav Republic of Macedonia and 5% in Turkey (no regional data available); the highest share of online purchases among the candidate country regions for which data are available was 17% in Jadranska Hrvatska (Croatia).

Measures of dispersion indicate that the incidence of online purchasing in Sweden, Finland, Austria and Denmark was relatively evenly spread across the regions (at NUTS level 2), whereas in Romania and Bulgaria, and to a lesser extent Italy and Greece (NUTS level 1 regions), there was a less regular regional pattern.

Data sources and availability

EU statistics on the use of ICT are based on a Regulation concerning Community statistics on the information society. The Regulation concerns statistics on the use of ICT in enterprises and statistics on ICT use in households and by individuals — only the latter are presented in this article.

Regional ICT data for a limited list of indicators have been available at the NUTS level 1 since 2006 as a voluntary contribution by the EU Member States and since 2008 on a mandatory basis. Some Member States provide regional data at NUTS level 2 on a voluntary basis. For the household/individual survey, questions on access to ICT are addressed to households, while questions on the use of ICT are answered by individuals within the household. As well as a core part, the model questionnaire includes a special focus which is changed each year. The scope of the household/individual survey comprises individuals aged between 16 and 74 years and households with at least one member within this age range. The reference period is the first three months of the calendar year.

The term broadband connection refers to the speed of data transfer for uploading and downloading data.

Broadband requires a data transfer speed of at least 144 kbit/s. The technologies most widely used for broadband access to the Internet include digital subscriber lines (DSL) and cable modems.

Internet users are persons who have used the Internet within the three months prior to the survey being conducted. Regular Internet users have used the Internet at least once a week within the three-month reference period.

E-commerce via the Internet is defined as placing orders for goods or services via the Internet. Purchases of financial investments, for example shares, confirmed reservations for accommodation and travel, participation in lotteries and betting and obtaining payable information services from the Internet or purchases via online auctions are included in the definition. Orders placed by manually typed e-mails are not counted. Delivery or payment by electronic means is not a requirement for an e-commerce transaction.

Context

During the course of recent decades, ICTs have penetrated all areas of economic and social life; they are credited with transforming societies in a profound and unprecedented way. With access to the Internet, it is very easy to obtain information about almost any topic, as search engines provide rapid and easy access to websites and information sources. Many other activities, such as communicating, consuming media and buying or selling goods and services, can be performed online. For example, it is possible to maintain contact with family members or friends via social networking sites, share holiday pictures on the web or have a video call with a friend via the Internet, while a growing share of retail sales are accounted for by online transactions. ICTs also facilitate working from home or other remote locations, delivering greater flexibility in work organisation. These developments have created new dimensions of economic, social or political participation for individuals and groups and the ubiquitous presence of ICTs has the potential to create completely new ways of participating in the economy and society.

As a basic condition, the participation of citizens and businesses in the information society depends on access to ICTs, for example the presence of electronic devices, such as computers, and fast connections to the Internet. The term digital divide has been coined to distinguish between those who have access to the Internet and are able to make use of services offered on the World Wide Web and those who are excluded. The term explicitly includes access to ICTs as well as the related skills needed to participate in the information society. The digital divide can be classified according to criteria that describe the difference in participation according to sex, age, education, income, social group or geographic location. For example, regular use of the Internet and, in particular online purchases, are often found to be less common in rural/remote regions.

Policies within the EU, both nationally and for the EU as a whole, have acknowledged the importance of bridging the digital divide to give all citizens equal access to ICTs and to enable them to participate in the information society. In May 2010 the European Commission adopted its Communication concerning 'A Digital Agenda for Europe' (COM(2010) 245 final), a strategy for a flourishing digital economy by 2020. The Digital Agenda for Europe is one of the seven flagship initiatives under the Europe 2020 strategy for smart, sustainable and inclusive growth. It outlines policies and actions aimed at maximising the benefit of the digital era to all sections of society and the economy. The agenda focuses on seven priority areas for action: creating a digital single market, greater interoperability, boosting Internet trust and security, providing much faster Internet access, encouraging investment in research and development, enhancing digital literacy skills and inclusion, and applying ICT to address challenges facing society like climate change and the ageing population. Examples of expected benefits include easier electronic payments and invoicing, rapid deployment of telemedicine and energy efficient lighting.

The Digital Agenda emphasises the quality of services in its targets: all households should have broadband subscriptions at a minimum speed of 30 Mbps by 2020 and 50% of households should have subscriptions at a speed of at least 100 Mbps. A set of key benchmarking indicators are defined in the European Commission's ' [Framework for benchmarking Digital Europe 2011-15](#) ', which is used to monitor the development of the European information society and achievements with respect to policy objectives set out in the Digital Agenda.

The Digital Agenda also puts emphasis on online shopping, with a focus on achieving a digital single European market. Policy measures aim to lower national barriers for online markets by opening access to content, such as buying and downloading digital media content, simplifying cross-border transactions and payments, and building trust in cross-border e-commerce.

Postal service statistics - universal service providers

Data from June 2011, most recent data: Further Eurostat information, Database .

This article takes a look at the **European Union (EU)** postal statistics from 2004 to 2009 covering the **universal service providers (USP)**, the companies operating under the 'Universal service obligation'.

Eurostat restarted the collection of data on postal services in 2005. The main priority of EU policies on postal services is to complete the **internal market** and ensure efficient, reliable and good-quality service at affordable prices for citizens and enterprises. Key elements of these policies are: gradual opening of the market to competition, guaranteed access to the **universal postal service**, cost transparency, reduction of the postal reserved areas, setting common quality standards of services, harmonisation of technical standards and creating conditions for rapid technological progress.

Main statistical findings

Highlights :

- domestic postal turnover growing slower than GDP ;
- share of postal employment decreasing;
- network access varies considerable across countries;
- number of letter-post items sent per capita declining in most countries;
- high rate of on-time delivery of priority letters ;
- large differences between the prices for posting a standard letter (domestic and intra-EU services).

Domestic postal turnover

Domestic postal turnover growing slower than the GDP

Austria had in 2009 the highest turnover from domestic postal sector in relation GDP (0.9%), being followed by Sweden, Denmark and Belgium, all with turnover percentages in GDP above 0.6%. At the other end of the scale is Bulgaria, with a turnover ratio to GDP of only around 0.1%. Although domestic postal turnover in absolute terms (expressed in current prices) has generally increased compared to 2004, its ratio to GDP fell in most countries. The ratio of domestic postal turnover to GDP fell most compared to 2004 in Sweden and Estonia.

Postal employment

Share of postal employment decreasing

The postal sector accounted in 2009 for 0.5% of total [EU-27 employment](#) . France had in 2009 the highest share of postal employment in total (1%), being followed by Finland and Hungary, with shares of 0.9% and 0.8%, respectively. Lowest shares (below 0.3%) were registered in Bulgaria, Greece, Cyprus and Portugal. Compared to 2004, postal employment in absolute terms decreased in the majority of countries, with its share in total employment following the same pattern. The countries where the shares fell most compared to 2004 were France, Austria and Sweden.

The average [productivity](#) measured in terms of turnover per person employed varies significantly among countries, ranging in 2009 from EUR 3500 in Bulgaria to EUR 113000 in Austria.

Network access

Network access varies considerable across countries

Postal items may be deposited by customers for processing in postal services in different physical facilities. These [access points](#) include [post offices, agencies and outlets](#) , [mobile post offices](#) , [letter boxes](#) , [post office boxes](#) and [places at which only stamps can be bought](#) . More than 100000 post offices (including [full-service post offices](#) , agencies, outlets, as well as mobile post offices) served the EU citizens needs in 2009.

Number of people served by one post office is an indicator for the access to network and it is calculated as the population divided to the number of post offices. In 2009, each post office served on average 3600 inhabitants in the EU-27. Network access was highest in Cyprus and the Czech Republic, with one post office serving less than 1000 inhabitants, whereas in the Netherlands, Belgium and Greece one post office served more than 7000 inhabitants. Compared to 2004, the network access significantly improved in Malta, Sweden and Hungary, whereas Latvia and Estonia showed the highest growth in the number of people served by one post office.

In 2009, there were 518000 letter boxes spread across the EU, corresponding in average to one per 715 inhabitants.

Number of letter-post items

Number of letter-post items sent per capita declining in most countries

In 2009, Spain and the Netherlands handled the highest number of letter-post items (for Germany, France, Italy and the United Kingdom no data were available). Nevertheless, compared to 2004 the number of letter-post items dropped in both these countries by 7% and 16%, respectively. Postal traffic declined by more than 20% in 2009 compared to 2004 in Bulgaria, Denmark and Malta.

The analysis of postal traffic in relation to the population data shows that the highest number of letter-post items sent per capita in 2009 was recorded in Finland (375) and Luxembourg (373), followed by the Netherlands

and Sweden, each with more than 200 items distributed per capita. In contrast, eleven EU Member States distributed less than 100 letter-post items per capita, with five of them – Bulgaria, Latvia, Lithuania, Poland and Romania - sending below 50.

The number of letter-post items handled per capita declined in most countries compared to 2004, while in Cyprus 20% more items per capita were sent in 2009.

With 120000 letter-post items distributed per person employed in 2009, Luxembourg maintained its first position as in 2004 and it is followed by Finland, Portugal and the Netherlands, each with more than 80000. On the other hand, Bulgaria showed the lowest number in both years (7000 in 2009 and 9000 in 2004).

Almost all letter-post items sent in Cyprus and Ireland in 2009 were [ordinary letters](#) and postcards (more than 90%), whereas in Estonia, Lithuania, Malta and Finland this share was below 50%. Compared to 2004, the share of ordinary letters and postcards in the total letter-post items fell significantly in Bulgaria and Poland. The most important rise was observed for Romania and Slovakia.

[Reserved area](#) refers to services for which the USPs enjoy exclusive rights to operate. The scope of the reserved area is defined in terms of deliveries within specific weight/price limits. All mail that falls outside the area reserved to USP may be handled by any other postal business operating in the market.

To illustrate the magnitude of the reserved area by country, the share of letters delivered in the reserved area as a share of all letters delivered by the USP is presented. These data give an indication on the share of the USP monopoly over a certain part of the postal market. As national definitions for the reserved area vary, comparison between countries is limited. Mail deliveries in the reserved area ranged from 29% of letter-post services in Malta up to 92% in Hungary.

On-time delivery of priority letters

High rate of on-time delivery of priority letters

On-time delivery of priority letters is a quality indicator of postal service showing the share of letters delivered within the time limits defined by the national performance indicators in the total of all letters sent. Due to variations in national performance standards (ranging from 1 to 3 working days elapsing between the date of deposit and the date of delivery to the addressee), size of the country, population density, etc., the quality of service data is not directly comparable across all countries. The share of priority letters delivered on time according to national performance indicators in 2009 was for the majority of countries above 90% or close to it.

Prices for posting a standard letter

Large differences between the prices for posting a standard letter (domestic and intra-EU services)

In order to compare the prices for posting a standard letter for domestic and intra-EU services across countries, the prices collected in national currency have been converted into euro using the annual average exchange rate.

Prices paid in 2009 by customers sending standard letters to national destinations via mail varied considerably across the EU, by a factor of 4. Malta and Romania offered the lowest national prices at EUR 0.19 and EUR 0.24 per item. The highest prices were observed in Finland (EUR 0.80) and Denmark (EUR 0.74).

For intra-EU cross-border traffic the highest prices were found in Sweden (EUR 1.13) and Denmark (EUR 1.07), about 3 times the tariff applied in Malta (EUR 0.37). Posting a domestic standard letter was in 2009 as expensive as an intra-EU letter in Finland, while intra-EU prices were about twice as high as domestic ones in Hungary, Romania and Sweden.

To adjust the prices to the purchasing power in each country the [purchasing power parities](#) for the individual consumption of households have been used. The data actually show the price to pay for posting a standard letter (domestic and intra-EU services) within each country in comparison to the general price level of the country.

Relative to the general price level, posting domestic letters was most expensive in Bulgaria, Slovakia and Poland and least expensive in Malta, Spain and Slovenia. Intra-EU services were most expensive in Bulgaria, Slovakia and Hungary and cheapest in Malta.

Data sources and availability

Eurostat restarted collecting data on postal services in 2005. The National Regulatory Authorities (NRAs) are Eurostat's partners in the data collection. The definitions of variables were discussed and agreed in cooperation with the European Postal Regulators in a project group ("Assistance and development of EU statistics") of the European Committee for Postal Regulation (CERP).

The data presented here cover the companies operating under the Universal Service obligation (universal service providers - USP). "Universal service" refers here to the set of general interest demands to which services such as the mail should be subject throughout the Community. The aim is to ensure that all users have access to quality services at an affordable price.

All variables used in this article were collected in the context of the "EU Postal Survey" of Eurostat, on the basis of annual questionnaires covering the USPs in the participating countries. Participating countries are the 27 EU Member States, Croatia, the Former Yugoslav Republic of Macedonia, Iceland and Norway. The data was provided by the National Regulatory Agency of each country.

Notes concerning figures and tables

See [list of country codes](#) .

Figures *italic* are estimates provided by the countries.

Table 1

- Turnover from domestic postal sector: 2009 data for DE refer to the leading market player.
- GDP: Gross domestic product at market prices.
- Employment in the domestic postal sector: data for DK are reported up to 2008 in head count, from 2009 in [full-time equivalents](#) ; 2009 data for DE refer to the leading market player; data for EE included up to 2007 all employed persons (i.e., also persons employed in other activities such as financial services), from 2008 data refer only to persons employed in postal and postal related services.
- Total employment: domestic concept, [ESA95](#) .
- Post offices: 2009 data for DE refer to the leading market player.
- Population: for each reference year, the population data on 1 January of the next year has been used.

Table 2

- Turnover, employment and post offices: see note Table 1.

Table 3

- Ordinary letters and postcards: including direct mail for DK, CY, LV and SE; 2009 data for DE refer to the leading market player; data for MT up to 2008 include direct mail; including registered mail and insured mail for FI.
- On-time delivery: the standard measured is D+1 (day plus one), with the following exceptions: ES D+3, RO D+2 for 2006 and 2007, SI D+2 for 2004, HR D+3 for the period 2004-2006. DE: 2009 data refer to the dominant market player.
- List price standard letter: prices might not be comparable across countries due to different pricing systems used, either pricing according to weight or pricing according to format. The data received in national currencies have been converted into Euro using the annual average exchange rates. 2009 data for DE refer to the leading market player. The data presented for MK for intra-EU prices refer to international service.

- PPPs: see note Figure 11.

Context

The purpose of Community policy in the postal sector is to complete the internal market for postal services and to ensure, through an appropriate regulatory framework, that efficient, reliable and good-quality postal services are available throughout the European Union to all its citizens at affordable prices. The importance of postal services both for the economic prosperity and social well-being and cohesion of the EU make this a priority area for Community action.

The Community framework for EU postal services is set out in [Directive 97/67](#) as amended by [Directive 2002/39](#) and as amended by [Directive 2008/06](#) (3rd Postal Directive). The improvement of quality of service, in particular in terms of delivery performance and convenient access are fundamental aspects of the EU postal policy. The Commission monitors and ensures the correct implementation of the regulatory framework and, where appropriate, proposes changes to this framework in order to achieve the Community's postal policy objectives. The above-mentioned directives provide the European legal framework with which the national regulatory authorities are to accelerate and promote the opening of markets.

The process of liberalising the postal services market in the EU was initially set in motion by the Green Paper on the development of the single market for postal services in 1992, as part of the goal to create a European single market. The aim was to get national monopolies to open up to competition in order to make postal services cheaper, faster, more efficient and more innovative, harmonise performance across EU Member States and improve the quality of cross border-services.

The ongoing process of liberalisation has brought about a gradual reduction of reserved postal services. Most of the Member States (Austria, Belgium, Bulgaria, Denmark, Estonia, Finland, France, Germany, Ireland, Italy, Netherlands, Portugal, Slovenia, Spain, Sweden and the United Kingdom) should have reached the complete liberalisation of the postal sector as of January 1, 2011, while for the rest of the Member States the deadline is extended as of January 1, 2013.

This article looks at [European Union \(EU\)](#) postal service statistics that cover [universal service providers \(USPs\)](#) , in other words the postal service providers operating under the [universal service](#) obligation. [Eurostat](#) restarted the collection of data on postal services in 2005.

The main priorities for EU policies on postal services include the completion of the [internal market](#) and ensuring efficient, reliable and good quality services at affordable prices for individuals and enterprises. Some of the key elements of EU policy in this area include: the gradual opening of the market to competition, guaranteed access to the universal postal service, cost transparency, a reduction of the postal reserved area, setting common quality standards, harmonisation of technical standards, and creating conditions for rapid technological progress.

Main statistical findings

Incomplete data for some EU Member States means that it is not always possible to provide EU-27 aggregates for postal indicators. Based on the information that is available for 19 Member States between 2004 and 2010, current price turnover in the EU's postal sector contracted by 6.9% overall – in part, reflecting the growing pressure from the emergence of [ICT](#) substitutes such as SMS (short message service), e-mail, chat rooms, VOIP (voice over internet protocol) and video alternatives.

Domestic turnover in the postal sector increased strongly between 2004 and 2010 in Lithuania and Latvia, rising overall by more than 80% in both of these Member States; relatively large increases were also recorded in

Poland, Hungary, Slovenia and Cyprus. In contrast, turnover fell by more than 10% between 2004 and 2010 in Estonia, Germany and Sweden; while the largest contraction in sales was reported in Bulgaria (-24.9%) – see Table 1; note that all of the German data for 2010 relates solely to the leading operator.

In relative terms (see Figure 1), the turnover derived from domestic postal services in 2010 peaked at a level equivalent to 0.65% of GDP in Sweden; the latest available data for Finland and France indicates slightly higher ratios although it should be noted that this dates from 2007. Belgium, Denmark, Austria and the United Kingdom were the only other EU Member States where sales from the postal sector reached a level equivalent to 0.5% of GDP or more. The ratio of turnover to GDP fell in the majority of Member States between 2004 and 2010; this was particularly the case in Sweden, Estonia and Luxembourg (2004 to 2008). There were eight EU Member States that reported the ratio of turnover to GDP rising between 2004 and 2010 (or nearest available years) – gains were generally modest, other than in Romania, where the relative weight of turnover from the postal sector doubled from 0.13% of GDP to 0.26% (between 2005 and 2010).

The postal sector in the EU-27 employed in excess of 1.0 million persons in 2010 (no recent data available for Ireland or Italy, 2009 data for France). France had the largest workforce in the postal sector, totalling 252000 (2009 data), far ahead of Germany's 171000 persons employed (estimate; again this figure is only for the leading operator) and the United Kingdom's 168000 (both these latter values are for 2010). France's postal workforce was not just large in absolute terms, it also represented a high, albeit declining, share (0.9%) of the total workforce – see Figure 2. Between 2004 and 2010 employment in the postal sector decreased in the majority of EU Member States. Based on information that is available for 24 Member States, the EU's postal workforce contracted by almost 10% between 2004 and 2010. An analysis by Member State shows that the largest reductions in the number of persons employed in the postal sector were recorded in Estonia, Denmark (both have breaks in series), Latvia and Sweden, where employment in the postal sector fell by at least 20%. In contrast, the number of persons employed in the postal sector grew in eight of the Member States, most noticeably in Hungary (10.4%) and Slovakia (8.9%).

Postal items may be deposited by customers for processing in different physical facilities. These [access points](#) include [post offices, agencies and outlets](#) , [mobile post offices](#) , [letter boxes](#) , [post office boxes](#) and [places at which only stamps can be bought](#) . Table 2 provides an overview of the number of post offices, while Figure 3 gives an indication of the density of the post office network relative to population size. The average number of inhabitants served by a post office in 2010 ranged from 1500 or less in Sweden, Luxembourg, the Czech Republic or Cyprus to one post office for more than 7500 inhabitants in the Netherlands and Belgium which are both densely populated countries.

In 2010, the largest operator in Germany handled the highest number (around 14700 million) of letter-post items; note that no recent data are available for the three next largest EU Member States – aside from a figure of 5474 million items for Italy in 2006. Otherwise, Spain and the Netherlands recorded the highest number of letter-post items (4459 and 4293 million respectively) – see Table 2. Between 2004 and 2010 the number of letter-post items dropped by 20% or more in Bulgaria, Denmark and Malta, and fell in 13 other Member States (data are available for 20 Member States). The number of letter-post items increased in four Member States between 2004 and 2010, with relatively modest increases recorded in Ireland and Luxembourg, while much larger gains were recorded in Latvia (23.1%) and Cyprus (33.8%).

An analysis of postal traffic in relation to population data shows that Finland and Luxembourg recorded the highest number of letter-post items per inhabitant in 2010 (around 360 items per inhabitant), while the only other EU Member States to record more than 200 letter-post items per inhabitant were Austria, the Netherlands and Sweden – see Figure 4. In contrast, 12 Member States handled less than 100 letter-post items per inhabitant, with Bulgaria, Romania, Lithuania, Latvia and Poland averaging less than 50 items per inhabitant.

Data sources and availability

The data presented in this article cover postal service providers operating under the universal service obligation, known as universal service providers. In this context universal service refers to the set of general interest demands to which services such as the mail should be subject throughout society – the aim of such an obligation is to ensure that all users have access to quality services at an affordable price.

Eurostat restarted collecting data on postal services in 2005. All data presented in this article are based on Eurostat's EU postal survey. The data was provided by the national regulatory authorities in each partici-

pating country, including the EU Member States, Iceland, Norway, Croatia and the former Yugoslav Republic of Macedonia.

Context

The purpose of EU policy in the postal sector is to complete the internal market for postal services and to ensure, through an appropriate regulatory framework, that efficient, affordable, reliable and good quality postal services are available throughout the EU for all citizens and enterprises. The importance of postal services both for the economic prosperity and social well-being and cohesion of the EU make this a priority area for EU action. Fundamental aspects of the EU's postal policy include a desire to improve the quality of service made available, in particular in terms of delivery performance and convenient access.

The process of liberalising the postal services market in the EU was initially set in motion by a Green paper on the development of the single market for postal services in 1992. Its aim was to open-up national monopolies to competition in order to make postal services cheaper, faster, more efficient and more innovative, harmonise performance across the EU Member States, and improve the quality of cross border-services. The EU legal framework for postal services is set out in [Directive 97/67](#) and subsequent amendments. The ongoing process of liberalisation has brought about a gradual reduction of reserved postal services. Most of the Member States were due to reach a state of complete liberalisation of their postal sectors as of 1 January 2011, although some were afforded a deadline some two years later.

The [European Regulators Group for Postal Services](#) was established in August 2010 by the European Commission. This group will advise and assist the European Commission, and its establishment is expected to strengthen cooperation between the national regulatory authorities and thereby help to develop best practices.

Table 3: Indicators of the European postal market 2004-2007[3]

The main priority of EU policies on postal services is to ensure efficient, reliable and good-quality service at affordable prices for the citizens and enterprises of the [European Union](#), through an ongoing process of liberalization.

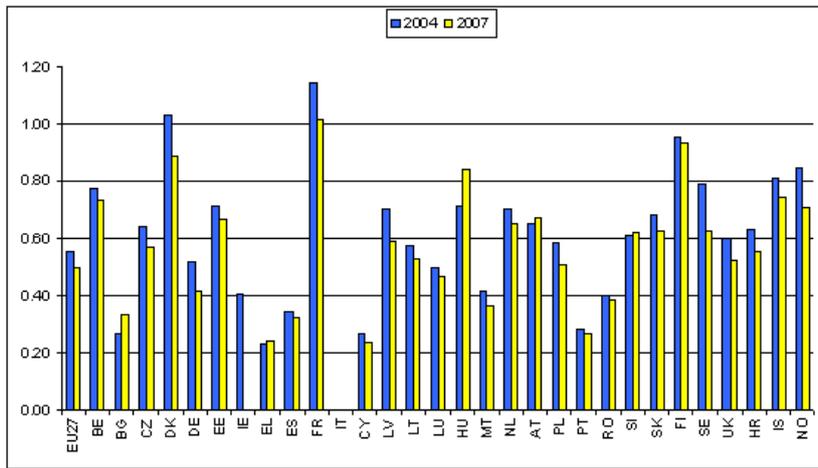

[Eurostat](#) has restarted collecting data on postal services in 2005. This article takes a look at the resulting postal statistics from 2004 to 2007. The data collection covers the [Universal service providers \(USP\)](#) the companies operating under the 'Universal service obligation'. For countries where a USP no longer exists, the company which was the USP prior to liberalization is referred to.

Main statistical findings

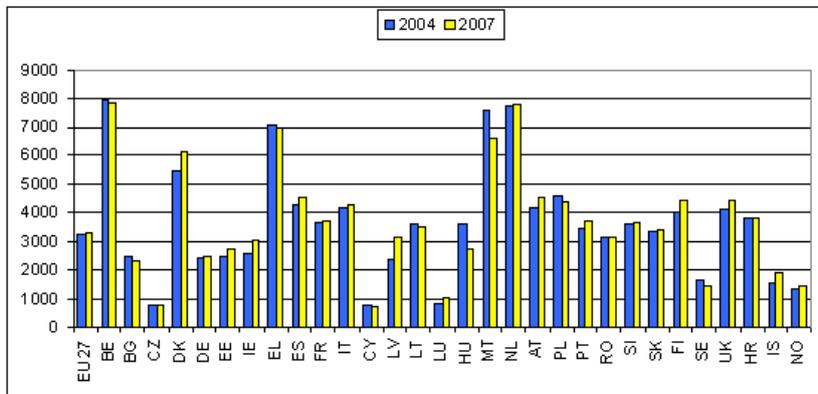

- Domestic postal turnover growing slower than the GDP during the period 2004-2007
- Share of postal employment decreasing in the EU-27 in 2007 compared to 2004
- Network access (number of inhabitants served by post offices) varies considerable between countries
- Significant differences between countries concerning the number of letter-post items sent per capita
- High rate of on-time delivery of priority letters in most countries
- Large differences between the prices for posting a standard letter (domestic and intra-EU services)

Graph 1: Total turnover from the domestic postal sector as % of GDP[4]

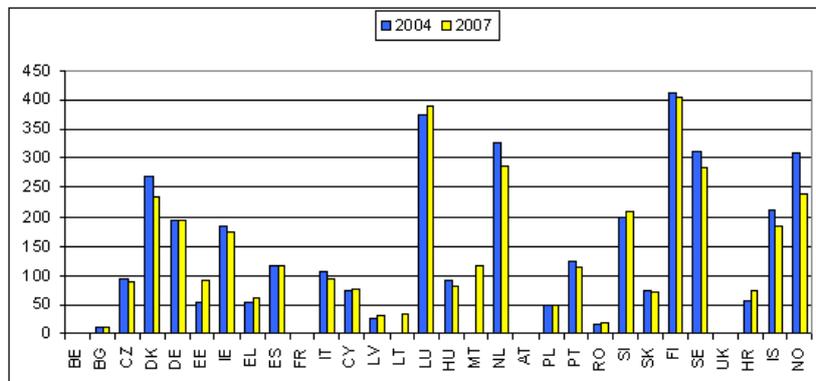

Graph 2: Total number of persons employed in the domestic postal sector as% of the total employment[5]

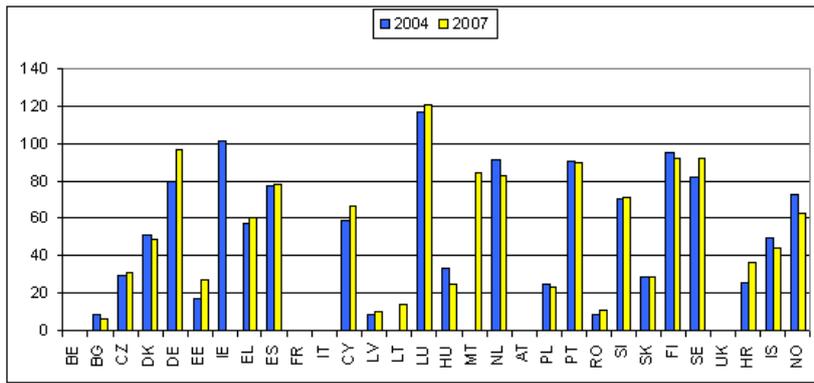

Graph 3: Number of people served by one post office (including postal agencies, postal outlets, as well as mobile post offices) 2004 2007[6]

	Post offices /postal agencies / postal outlets and mobile offices (ACC 202)	of which: Mobile offices (ACC 2023)	Letter boxes (ACC 203)	Post office boxes (ACC 204)	Points, at which only stamps can be bought (ACC 205)

Domestic postal turnover

Turnover growing slower than the GDP during the period 2004-2007

All EU national postal operators together generated in 2007 a turnover of EUR 60 billion, which amounts to approximately 0.5% of EU GDP. Almost 70% of the total turnover of the national postal operators was created in the four largest economies: Germany, France, United Kingdom and Italy, where the turnover ranged from EUR 13 billion (Germany) to EUR 5 billion (Italy). Larger countries tend to have higher turnover figures in absolute terms, and therefore turnover in relation to GDP has been used to facilitate comparison between countries.

Sweden remains in 2007 the country with the highest turnover from domestic postal sector in relation GDP (0.8%), followed by Denmark, France, Finland and Belgium, all with turnover percentages in GDP above 0.6%. At the other end of the scale are the two new EU Members States, Bulgaria and Romania, with turnover ratios to GDP of only around 0.1%. Although domestic postal turnover in absolute terms (expressed in current prices) has generally increased compared to 2004, its ratio to GDP fell in most countries, as well as at the EU-27 level. Countries where the ratio of domestic postal turnover to GDP fell most compared to 2004 were Estonia, Luxembourg, Sweden, Germany, the Netherlands and Norway. Only Lithuania and Italy have seen the domestic postal turnover in relation to GDP slightly growing in 2007 compared to 2004.

Postal employment

Share of postal employment decreasing in the EU-27 in 2007 compared to 2004

The national postal sector employed more than 1 million persons in 2007, accounting for 0.5% of total EU-27 employment. The number of persons employed compared to 2004 dropped by 6.5% in the EU-27, although this decline slowed down towards 2007. France had in 2007 the highest share of postal employment in total (1%), being followed by Finland, Denmark and Hungary, all with shares above 0.8%. Lowest shares (below 0.3%) were registered in Greece, Cyprus and Portugal. Compared to 2004, postal employment in absolute terms increased in several countries of the EU, as well as in Iceland. However, its share in total employment has followed the same pattern only in Hungary, Bulgaria, Austria, Greece and Slovenia. For the rest of the countries and the EU-27 it has decreased – the countries where the shares fell most compared to 2004 were Denmark, France, Sweden and Norway. The average productivity measured in terms of turnover per person employed in 2007 was EUR 54000 in the EU-27, almost 12% higher than in 2004. There are significant differences between the Member States, the productivity measured in terms of turnover per person employed ranging from EUR 2000 in Bulgaria to EUR 97000 in Sweden.

Network access

Network access (number of inhabitants served by post offices) varies considerable between countries

Postal items may be deposited by customers for processing in postal services in different physical facilities. These [access points](#) include [post offices, agencies and outlets](#) , [mobile post offices](#) , [letter boxes](#) , [post office boxes](#) and [places at which only stamps can be bought](#) . More than 150000 post offices (including [full-service post offices](#) , agencies, outlets, as well as mobile post offices) served the EU citizens needs in 2007 and this number remained more or less stable compared to 2004.

Number of people served by one post office is an indicator for the access to network and it is calculated as the population divided to the number of post offices. In 2007 each post office served on average 3300 persons in the EU-27. Looking at the data for individual countries large variations could be observed. Postal coverage (network access) was highest in Cyprus and the Czech Republic, with one post office serving less than 1000 inhabitants, whereas in Belgium and the Netherlands it was about 8 times lower. Compared to 2004 the network access significantly improved in Hungary and Malta, whereas Denmark and Latvia showed the highest rise in the number of people served by one post office. In 2007, there were 720 thousand letter boxes spread across the EU, corresponding in average to one per 690 citizens.

Number of letter-post items

Significant differences between countries concerning the number of letter-post items sent per capita

In 2007, Germany, Italy, Spain and the Netherlands handled the highest number of [letter-post items](#) (for France and the United Kingdom no data were available). Nevertheless, compared to 2004 the number of letter-post items dropped in Italy and the Netherlands by 8% and 11%, respectively. Norway's postal traffic in 2007 was also in decline compared to 2004 by more than 20%.

The analysis of postal traffic in relation to the population data shows that the highest number of letter-post items sent per capita in 2007 was recorded in Finland (406), followed by Luxembourg (388) and then by the Netherlands, Sweden, Norway, Denmark and Slovenia, each with more than 200 items distributed per capita. In contrast, twelve EU Member States distributed less than 100 letter-post items per capita, with five of them – Bulgaria, Latvia, Lithuania, Poland and Romania - sending below 50.

Among the countries with the highest number of letter-post items handled per capita (more than 200), only in Luxembourg and Slovenia an increase compared to 2004 was observed. However, the most notable increase is shown by Estonia and Croatia.

With 121 000 letter-post items distributed per person employed in 2007, Luxembourg maintained its first

position, being followed by Germany, Finland and Sweden, each with more than 90 000. On the other hand, Bulgaria showed in both years the lowest number (7000). Largest increase compared to 2004 was observed in Germany, Estonia, Sweden and Croatia.

Almost all letter-post items sent in Cyprus and Malta in 2007 were [ordinary letters](#) and postcards (more than 98%), whereas in Estonia, Finland, Germany, Lithuania and Luxembourg this share was only around 50%. Compared to 2004, the share of ordinary letters and postcards in the total letter-post items fell significantly in Estonia, Sweden and Poland. The most important rise was observed for Ireland and Romania.

[Reserved area](#) refers to services for which the USPs enjoy exclusive rights to operate. The scope of the reserved area is defined in terms of deliveries within specific weight/price limits. All mail that falls outside the area reserved to USP may be handled by any other postal business operating in the market.

To illustrate the magnitude of the reserved area by country, the share of letters delivered in the reserved area as a share of all letters delivered by the USP is presented. These data give an indication on the share of the USP monopoly over a certain part of the postal market. As national definitions for the reserved area vary, comparison between countries is limited.

On-time delivery of priority letters

High rate of on-time delivery of priority letters in most countries

[On-time delivery of priority letters](#) is a quality indicator of postal service showing the share of letters delivered within the time limits defined by the national performance indicators in the total of all letters sent. Due to variations in national performance standards, size of the country, population density, etc., the quality of service data is not directly comparable across countries. The national performance standards range in the countries from 1 to 3 working days elapsing between the date of deposit and the date of delivery to the addressee. The share of priority letters delivered on time according to national performance indicators in 2007 was for most of the countries above 90% or close to it.

Prices for posting a standard letter

Large differences between the prices for posting a standard letter (domestic and intra-EU services)

In order to compare the [prices for posting a standard letter](#) for domestic and intra-EU services across countries, the prices collected in national currency have been converted into euro using the annual average exchange rate.

Prices paid in 2007 by customers sending standard letters to national destinations via mail varied considerably across the EU, by a factor of 5. Malta and Slovenia offered the lowest national prices at EUR 0.14 and EUR 0.23 per item. The highest prices were observed in Norway (EUR 0.75), Denmark (EUR 0.74), and Finland (EUR 0.70).

For intra-EU cross-border traffic the highest prices were found in both Sweden and Norway (EUR 1.19), more than 4 times the tariff applied in Malta (EUR 0.27). Posting a domestic standard letter was in 2007 as expensive or almost as expensive as an intra-EU letter in Finland and Italy, while in Romania intra-EU prices were 2.5 times higher than the domestic ones.

To adjust the prices to the purchasing power in each country the [Purchasing power parities](#) for the individual consumption of households have been used. The data actually show the price to pay for posting a standard letter (domestic and intra-EU services) within each country in comparison to the general price level of the country.

The adjustment using the PPPs changes the price comparison significantly. Relative to the national price levels, posting domestic letters was most expensive in Poland, Lithuania and the Slovak Republic and least expensive in Malta, Slovenia and Spain. Intra-EU services were most expensive in Poland, Hungary and Lithuania and cheapest in Malta.

Data sources and availability

[Eurostat](#) restarted collecting data on postal services in 2005. The National Regulatory Authorities (NRAs) are Eurostat's partners in the data collection and the reference years are 2004 to 2008. This article covers years up to 2007. The definitions used were discussed and agreed in cooperation with the European Postal Regulators in a project group ("Assistance and development of EU statistics") of the European Committee for Postal Regulation (CERP).

The data collection covers the companies operating under the Universal Service obligation (Universal Service Providers - USP). For countries where a USP no longer exists, the company which was the USP prior to liberalisation is referred to. "Universal service" refers here to the set of general interest demands to which services such as the mail should be subject throughout the Community. The aim is to ensure that all users have access to quality services at an affordable price.

Only data on the USP have been published so far. Activities other than postal services (for instance financial services) of the USP are excluded due to the fact that they are not comparable between countries. Differing market conditions should be taken into consideration while making comparisons between countries.

All variables used in this article were collected in the context of the "EU Postal Survey" of Eurostat, on the basis of annual questionnaires covering the USP in the participating countries. Participating countries are the 27 EU Member States, Croatia, Iceland and Norway. The data was provided by the National Regulatory Agency of each country.

The data were collected for the period 2004-2008. However, 2008 data have not yet been validated and published.

Context

The purpose of Community policy in the postal sector is to complete the internal market for postal services and to ensure, through an appropriate regulatory framework, that efficient, reliable and good-quality postal services are available throughout the European Union (EU) to all its citizens at affordable prices. The importance of postal services both for the economic prosperity and social well-being and cohesion of the EU make this a priority area for Community action.

The Community framework for EU postal services is set out in [Directive 97/67/EC](#) as amended by [Directive 2002/39/EC](#) and as amended by [Directive 2008/06/EC](#) (3rd Postal Directive). The improvement of quality of service, in particular in terms of delivery performance and convenient access are fundamental aspects of the EU postal policy. The Commission monitors and ensures the correct implementation of the regulatory framework and, where appropriate, proposes changes to this framework in order to achieve the Community's postal policy objectives. The above-mentioned directives provide the European legal framework with which the national regulatory authorities are to accelerate and promote the opening of markets.

The process of liberalising the postal services market in the EU was initially set in motion by the Green Paper on the development of the single market for postal services in 1992, as part of the goal to create a European single market. The aim is to get national monopolies to open up to competition in order to make postal services cheaper, faster, more efficient and more innovative, harmonise performance across EU Member States and improve the quality of cross border-services.

The ongoing process of liberalization has brought about a gradual reduction of reserved postal services, and the complete liberalization of the postal sector is expected as of January 1, 2011 (2013 for some EU Member States). Five EU Member States have already fully liberalised their postal service markets: Germany, the Netherlands, Finland, Sweden and UK.
