Carbon Farming – MRV examples from Ireland

Dr. Michelle Kearney

Climate Change & Bioenergy Policy Division

Department of Agriculture, Food and the Marine

Overview of Irish Agriculture:

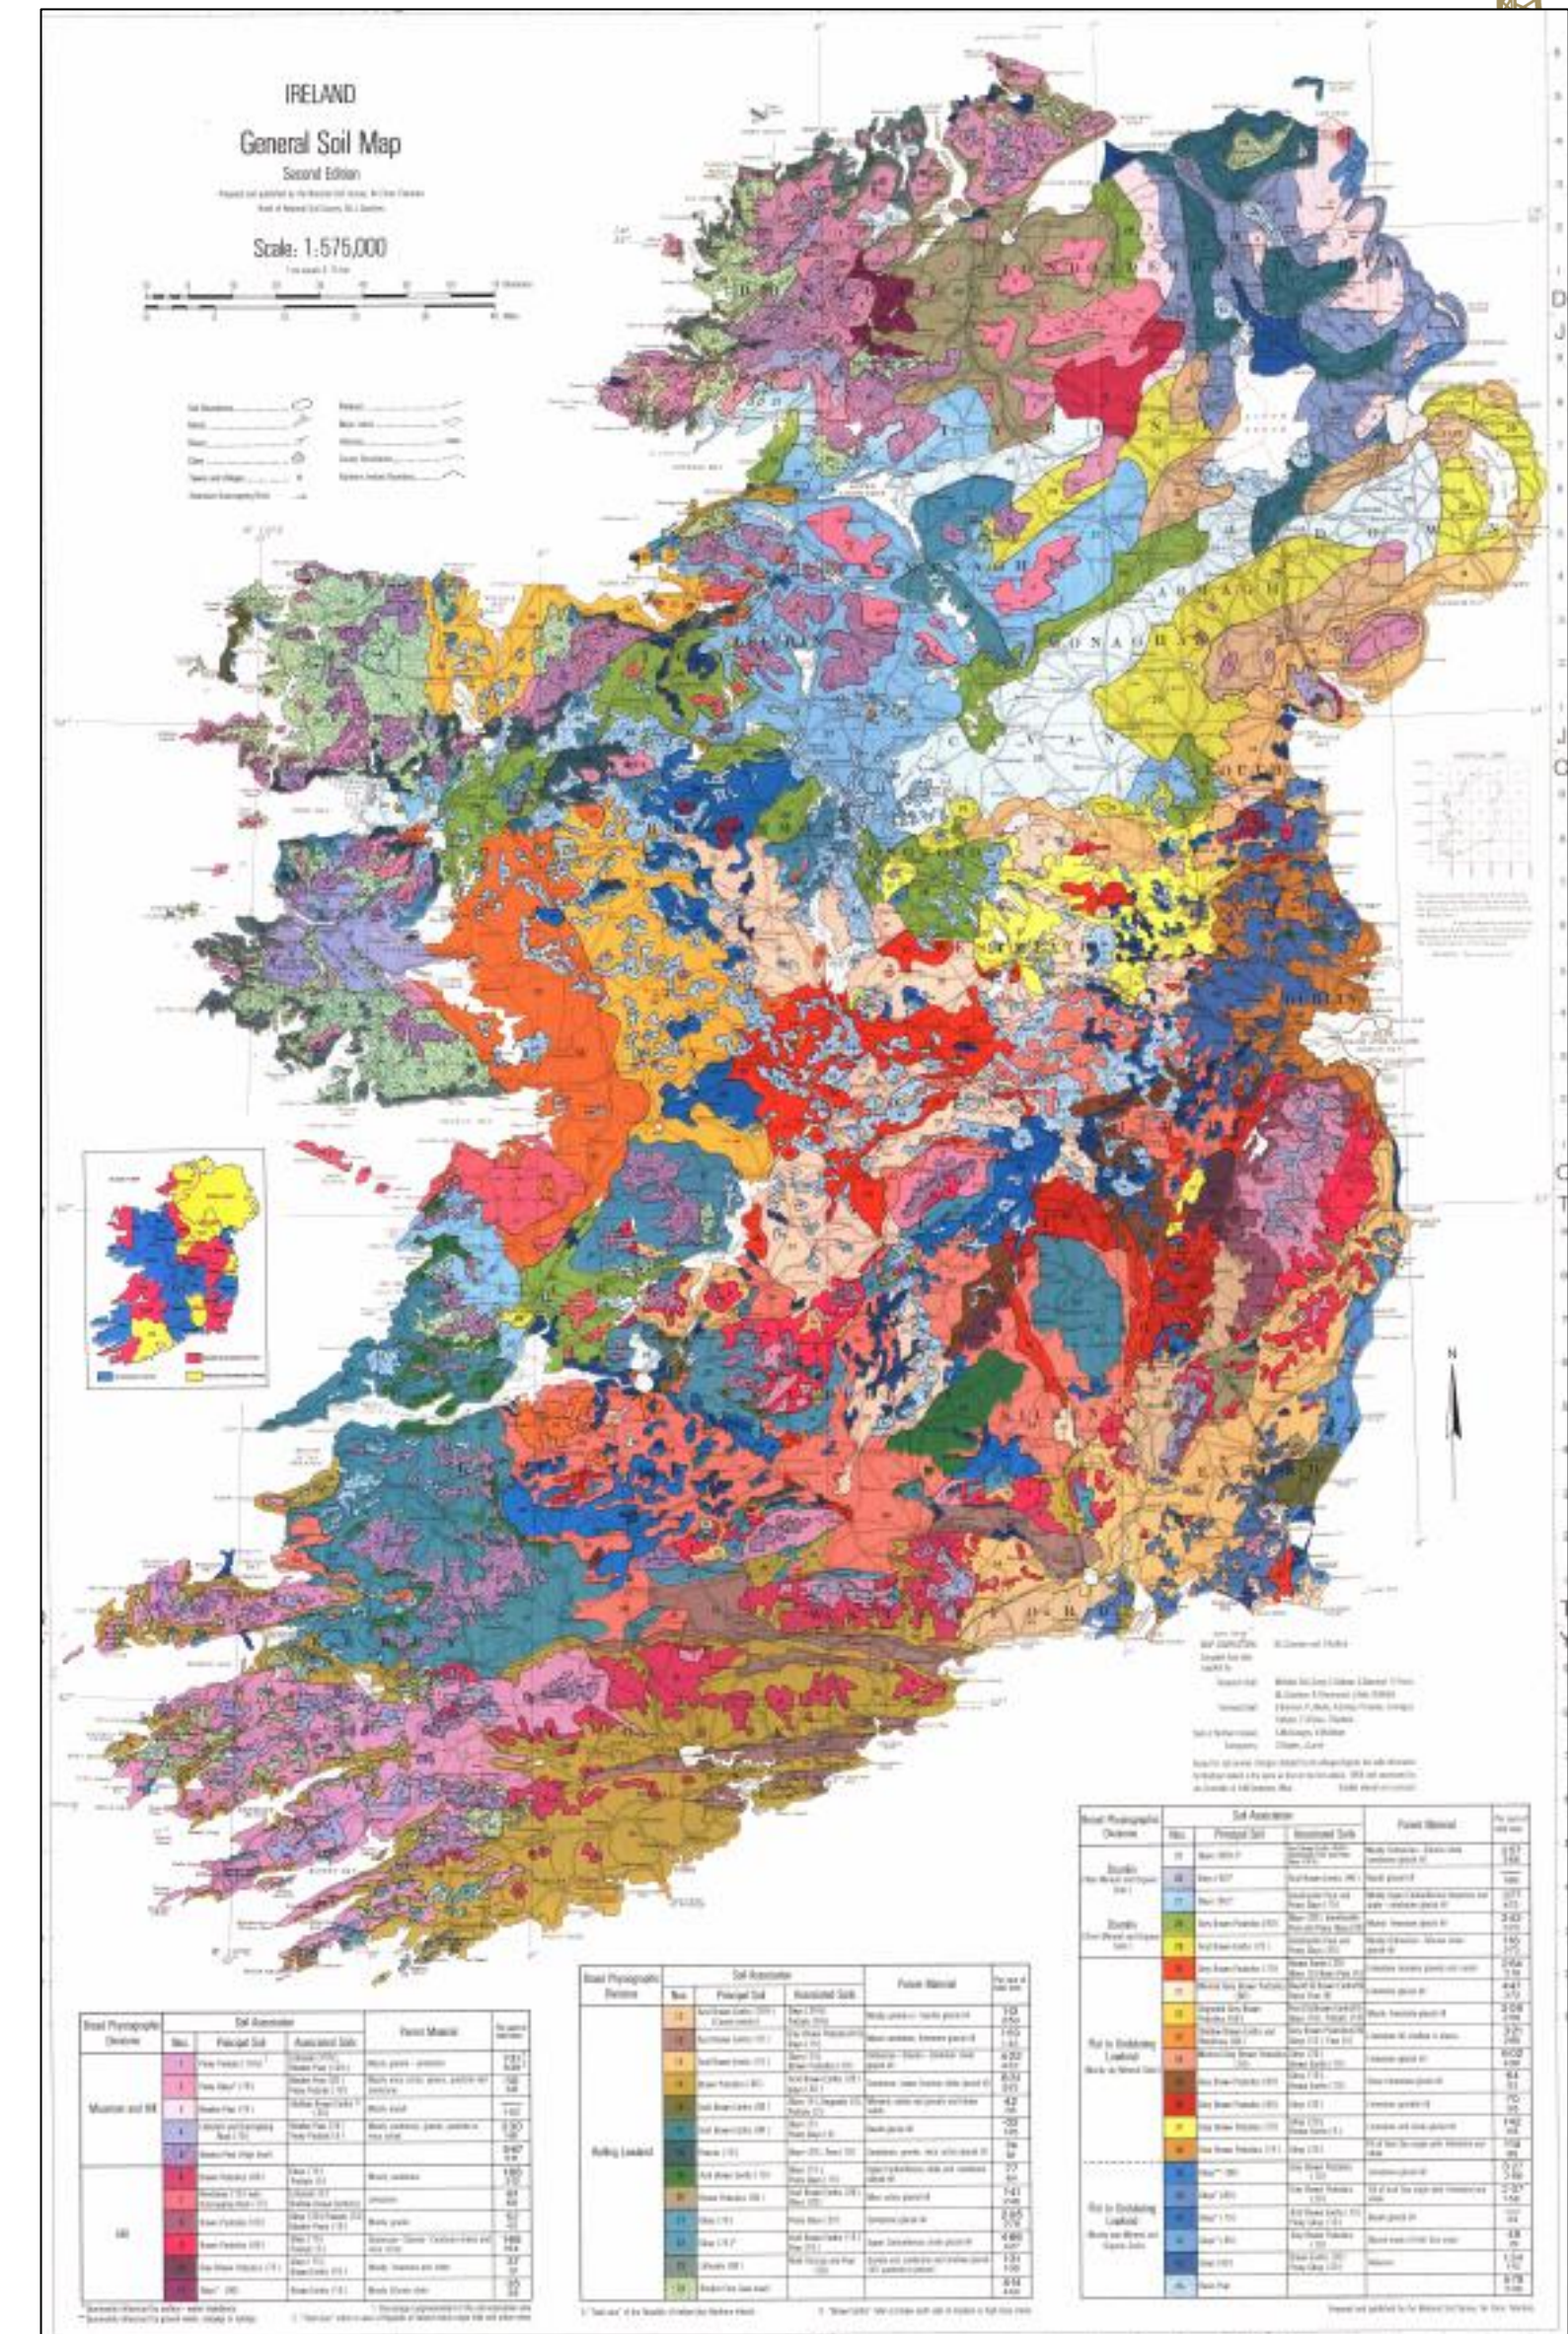

- Total land area of 6.9 million ha, of which 4.5 million ha is used for agriculture
- 92% of land is devoted to grazing and forage production with the remaining 8% attributable to crops, fruit and horticultural
- The agri-food sector is Ireland's largest indigenous manufacturing industry, accounting for over 173,000 jobs
- The sector is dominated by medium-sized farms and a maritime climate favours a grass-based system of agricultural production.
- High level of on-farm technical efficiencies make further GHG emission reductions challenging
- Carbon Farming represents one pathway to reward farmers for enhanced sequestration and carbon pool protection activities

How do we address knowledge gaps for land-based emissions?

- Higher resolution soil/landcover/drainage maps
- Improved activity data at field level
- Country specific GHG emission/removal factors for all soils types and agricultural management

RePeat Mapping Project

- Circa 300,000ha of drained organic soils under agricultural management
 - represents a significant source of national GHG emissions to which accurate maps are required
- Objectives of the RePeat Project:
 - The increased accuracy of peatland maps at a field scale level
 - The precise identification of agricultural land-use and intensity on former peatlands
 - Provide detailed information to policy makers to provide better management options to farmers to help reduce GHG emissions

National Soil Survey Pilot Programme

- The purpose of this programme is to develop a baseline national data set at farm level for :
 - *Macro- and micronutrients for agronomic advice and water quality risk assessment.*
 - *Soil carbon(C) relating primarily improving climate objectives and soil health.*
 - *Soil pathogen assessment as a biosecurity measure for policy guidance*
- Programme to help refine our soil maps and inform us on long term changes in Soil Organic Matter and therefore stock of carbon at a farm level.
- Farm Advisors will be up-skilled to assist farmers in implementing on-farm nutrient management practice ensuring that farmers know the right nutrient type, the right application rate, and when and where to apply fertiliser an organic manure.
- In driving soil health will improve the economic and environmental sustainability of farms and the ability to store and sequester carbon.

NASCO- National Agricultural and Soil Carbon Observatory

The establishment of this infrastructure will allow:

- Better quantification of soil GHG fluxes from agricultural land
- The inclusion of mitigation measures to increase carbon sequestration to be reflected in our national inventory
- Participation in the EU Integrated Carbon Observation System (ICOS)

NASCO- National Agricultural and Soil Carbon Observatory

- A network of Eddy Covariance Flux Towers funded by DAFM and industry and managed by Teagasc as part of their SignPost Farms
- A variety of sites including agricultural grasslands, mineral soils and peatlands
- Ability to determine actual emissions (CO₂ CH₄, N₂O) and sequestration in Irish specific conditions
- As a result, Ireland will have the highest density of agricultural flux tower installations per hectare in Europe

Farmed Peat EIPs

- A call for a new locally-led European Innovation Partnership (EIP) project/s on reduced management of farmed peatlands was announced in August 2020.
- Aim to provide lessons learned to scale up the actions and measures into a larger agri-environment programme for the next CAP.
- Local Groups to put forward projects outlining concrete actions that will;
 - Protect the carbon stock and restore sequestration associated with drained peatlands under agricultural management.
 - Maximise other ecosystem service co-benefits such as protection of biodiversity, water quality and water regulation.
 - Build resilience to the impacts of climate change at catchment/landscape level.
- Two groups, Nature Based Agri Solutions Limited (FarmPeat project) and Green Restoration Ireland were successful and will receive over €2 million to complete their projects.

FarmPEAT

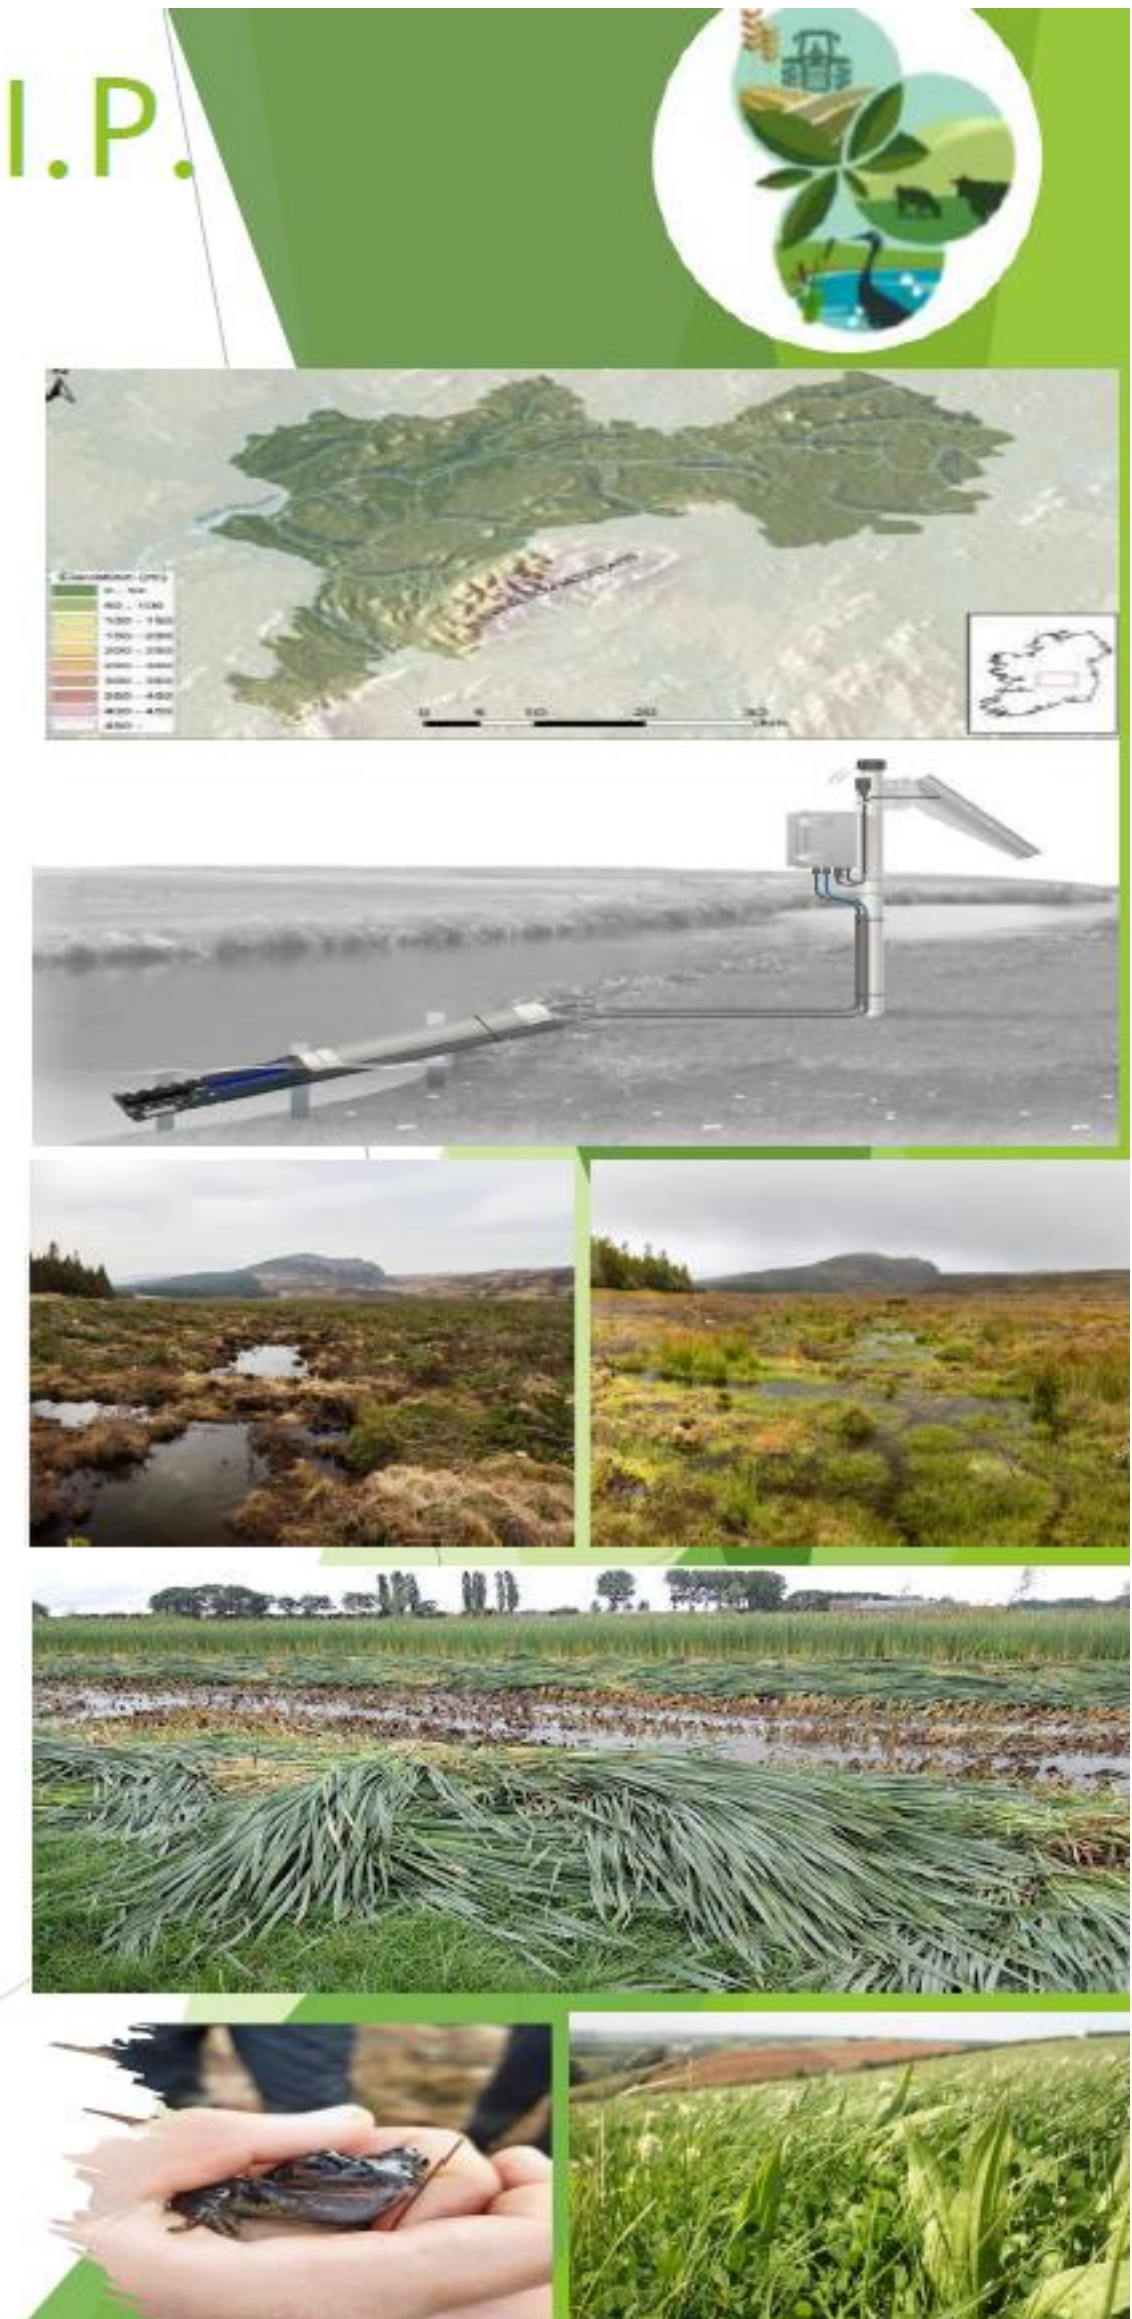

Farm Carbon E.I.P

Green Restoration Ireland : Farm Carbon E.I.P.

- Creation of an **Irish Peatland Code** to provide assurances to voluntary carbon market buyers that the climate benefits being sold are real, quantifiable, additional and permanent.
-  **LANDSCALE** assessment of Co. Offaly (Verra)
- A **Water Quality Monitoring Programme** employing Sonde devices and Autosamplers to monitor a peatland catchment (1st of its kind in Ireland on the Silver River in Co. Offaly)
- Trialing of Landowner-led **Peatland Restoration & 'Rewetting' Programme** by various 'rewetting' approaches i.e.,
 - Rewetting & Rewilding (e.g., Fen, Wet grassland etc.)
 - Partial Rewetting and
 - Paludiculture Trials (cattail)
- A Whole farm Plan approach i.e. a **Peatland Management & Sustainability Programme** including native woodland restoration, hedge repair, species action plans etc. multi-species Grass Swards cultivation employing mob grazing for adjacent lands

Terrain AI

Conclusions

- Good baseline data on soil carbon and field level activity is essential
- Long term emission flux data has widespread benefits and is now a prerequisite for future agricultural policy formation.
- Farmers need to understand why policy objectives are moving in a certain way- accurate data will aid this process
- There are opportunities for farmers, such as carbon farming, to financially benefit from this increased data collection
- We must continue to prove the sustainability of our production systems to ensure a vibrant agricultural sector for future generations.
