

# Risk Perception

James K. Hammitt

Harvard Center for Risk Analysis

# Disagreement Between Experts & General Public?

Public often accepts expert evaluations, but not always

- "Public" is large, diverse

Disagreement can go either direction

- Lay people perceive greater risk
  - Nuclear power & waste
  - Hazardous-waste sites
- Lay people perceive smaller risk
  - Avian flu, hurricanes
  - Dietary supplements

# Explaining Expert – Lay Disagreement

## Ideology

- Natural v. synthetic
- Large, globalized v. small, localized control
  - e.g., centralized power generation v. small-scale distributed sources

## Mistrust experts

- Corrupt, self-interested?
- History of inaccuracy (BSE?)

## Dual rationalities

- Experts – probability or expected value of harm
- Lay people – "psychometric" attributes, probability neglect
- Cognitive (slow, laborious) v. affective (rapid, intuitive)

# Psychometric Attributes

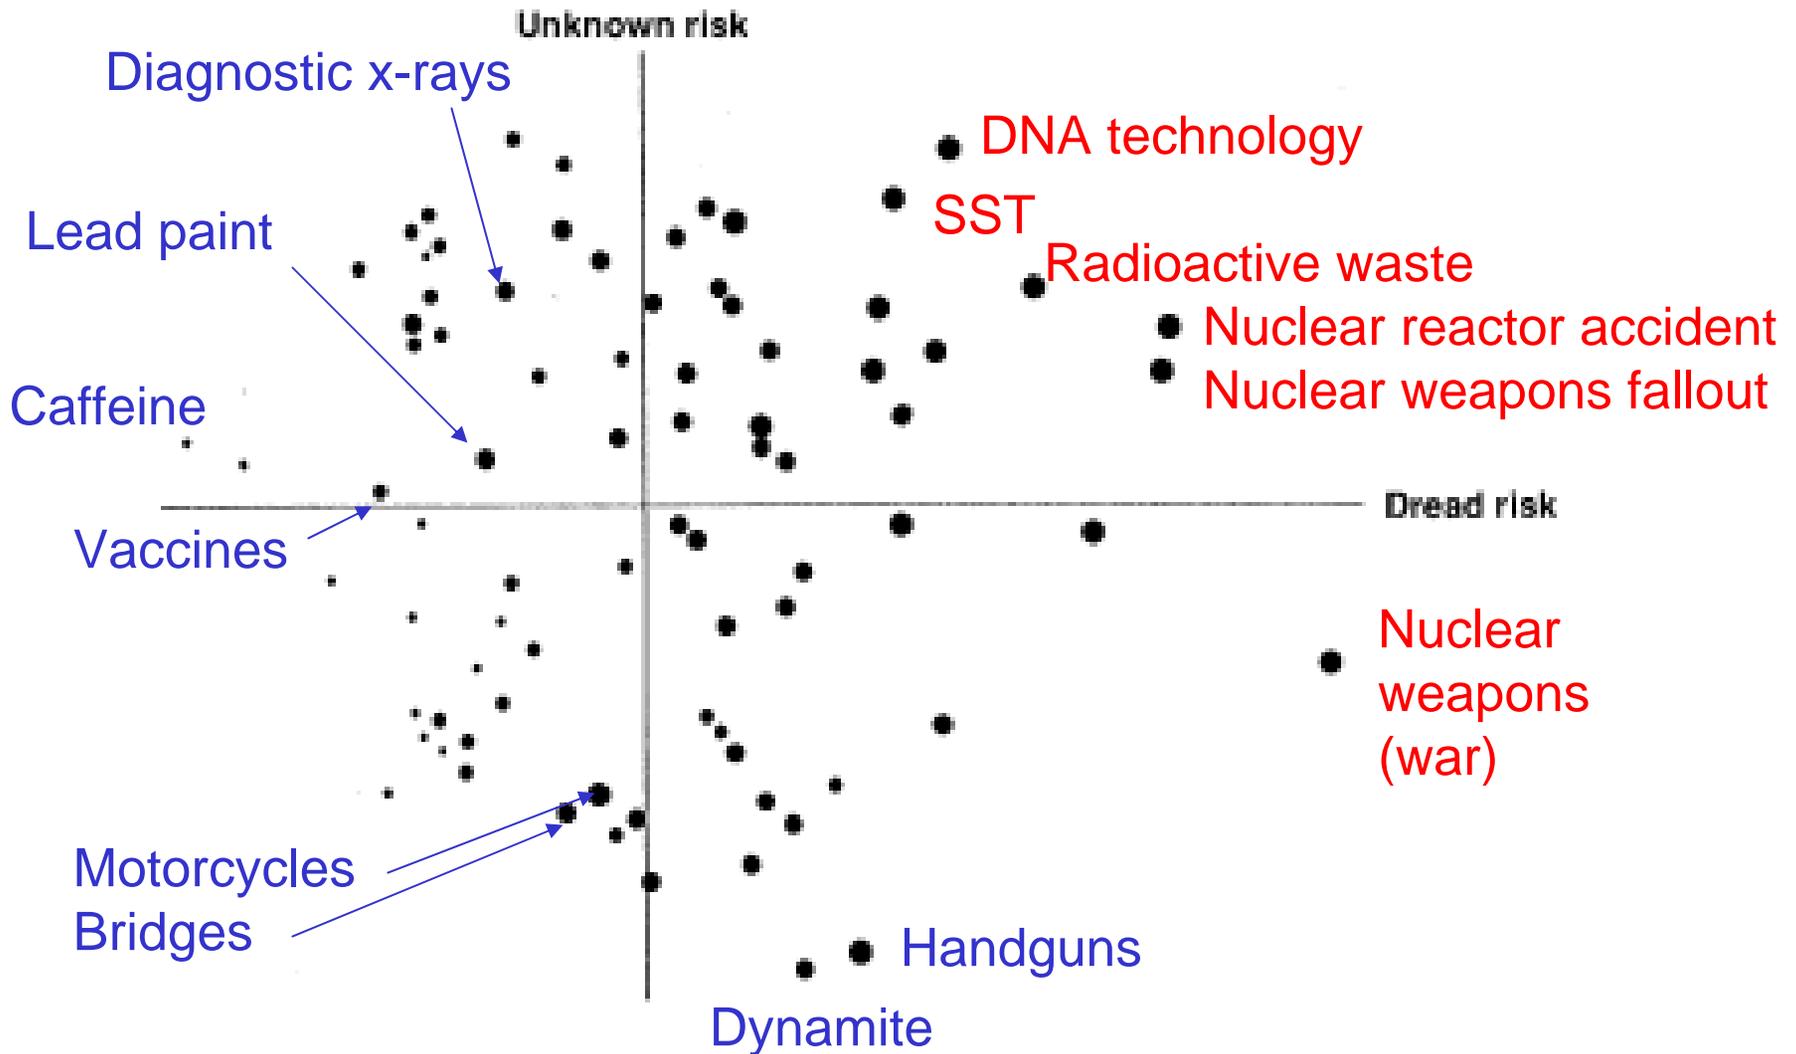

Factor analysis suggests multiple attributes may be condensed into two primary factors

## Dread

- Uncontrollable, involuntary, catastrophic, inequitable distribution of benefits, affects future generations

## Uncertain

- Unobservable, not understood scientifically, delayed consequences, newly recognized

Demand for regulation indicated by size of dot (Slovic 1987)

# Value of Reducing Risk: Modest Effect (at most)

## Hammitt & Liu 2004, Taiwan

- 100% premium for lung disease from air pollution v. liver disease from drinking water
- 30% premium for fatal cancer over similar non-cancer illness

## Jones-Lee & Loomes 1995, UK

- 50% premium for small-scale underground v. road

## Chilton et al. 2002, UK

- < 25% premium for rail, domestic or public fire fatalities v. road crashes

## Magat, Viscusi & Huber 1996, US

- No premium for terminal lymphoma v. automobile fatality

## Itaoka et al. 2006, Japan

- No premium for unlikely catastrophe (0.005/yr, 20,000 deaths) v. routine loss (100 deaths)

# Psychometric Attributes: Legitimate Concerns or Cognitive Errors?

## Expert models often over-simplified

- Ignore distribution of risks & benefits
- Omit non-fatal health effects
- Ignore individual control

## Informal evaluations often biased

- Framing: inconsistent responses to alternative logically equivalent descriptions
- Heuristics & biases

Both groups oversimplify toxicity – "the dose makes the poison" (Paracelsus)

# Framing

Flu next year forecast to cause 600 deaths

Choice: A or B?

- A. Save 400 for sure
- B. Save 600 with probability  $2/3$ , save none with probability  $1/3$

Choice: C or D?

- C. 200 die for sure
- D. None die with probability  $2/3$ , 600 die with probability  $1/3$

# Heuristics & Biases

(Tversky and Kahneman 1974)

In estimating probabilities & other quantities, people often rely on cognitive short-cuts (heuristics)

- Representativeness
- Availability
- Anchoring & adjustment

Helpful & efficient, but produce systematic biases

# Representativeness

Probability assessed by degree to which instance expresses characteristics of the class

Biases:

- Insensitivity to prior probability
- Insensitivity to sample size

# Insensitivity to Prior Probability

Dick is a 30 year old man. He is married with no children. A man of high ability and high motivation, he promises to be quite successful in his field. He is well liked by his colleagues.

Is it more likely that Dick is

- A lawyer?
- An engineer?

# Insensitivity to Prior Probability

Same estimates when drawn from:

- 70 lawyers and 30 engineers
- 30 lawyers and 70 engineers

Without (noninformative) description,  
people (correctly) report probability =  
prior probability

# Availability

Probability assessed by ease of producing examples

Biases:

- Retrievability
  - Salience of recently viewed traffic crash
- Efficacy of search set
  - More English words with "r" as 1<sup>st</sup> or 3<sup>rd</sup> letter?
- Imaginability
  - Imaginability of ways project could go bad need not be correlated with probability

# Anchoring & Adjustment

Estimate % of African states in UN

Sensitive to explicitly random starting value

- 25 (random seed = 10)
- 45 (random seed = 65)

# Overconfidence

Generally, people are overconfident (give confidence intervals are too narrow)

## “Surprise Index”

- Fraction of realizations outside the 0.01 and 0.99 fractiles
- If perfectly calibrated, 2%
- Often between 20 and 45%

# Ambiguity Aversion

Humans dislike ambiguous (uncertain) probabilities

- Risk of bad outcome
- Risk of bad probability

Should we take greater precaution when probabilities are uncertain?

- Conservative assumptions
- Worst-case analysis

# Perils of Prudence

(Nichols & Zeckhauser 1986)

Conservative assumptions, worst-case analysis, and ambiguity aversion can increase risk

| <u>Technology</u> | <u>Deaths</u> | <u>Probability</u> | <u>Expected deaths</u> |
|-------------------|---------------|--------------------|------------------------|
| Ambiguous         | 1             | 0.99               |                        |
|                   | 1,000         | 0.01               | 11                     |
| Sure              | 101           | 1.0                | 101                    |

Using upper-bound risk estimates, **Sure** would be preferred to **Ambiguous**

# Perils of Prudence

If decision is repeated for 10 pairs of technologies  
(and risks are independent)

| Technology | Deaths  | Probability |
|------------|---------|-------------|
| Ambiguous  | 10      | 0.904       |
|            | < 1,010 | 0.996       |
| Sure       | 1,010   | 1.0         |

Policy of choosing **Sure** (with smaller upper-bound risk) is almost certain to kill more people

# Quantifying Probability

Probability of harm from nanotechnology is "subjective"

- Quantitative measure of degree of belief
- Individuals can hold different probabilities for same event

All probabilities are subjective

- "Objective randomness" is really chaos (e.g., coin toss, roulette wheel)
  - Deterministic process
  - Sensitively dependent on initial conditions
  - Insufficient information about initial conditions

# Expert – Lay Disagreement: Explanation or Rationalization? (Margolis 1996)

## Ideology

- Need not imply disagreement about risk

## Mistrust experts

- Tautological?
- When are experts trusted or mistrusted?

## Dual rationalities

- Attribute ratings may be result of disagreement with experts, not cause
- Perceived benefits inversely associated with perceived risks (Sunstein)

# Perceived Risk Depends on Salience of Benefits and Danger (Margolis 1996)

|                 |     | Benefit salient?    |                        |
|-----------------|-----|---------------------|------------------------|
|                 |     | Yes                 | No                     |
| Danger salient? | Yes | Balance             | Better safe than sorry |
|                 | No  | Waste not, want not | Indifferent            |

# Conclusions

Experts and public sometimes perceive risk differently

- What explains when & direction of disagreement?

Attributes beyond probability & severity

- Distinguish legitimate concerns from cognitive error
- Rationale rather than predictor?

Saliency & distribution of benefits & harms are critical
