

Econometric analysis and counterfactual studies in the context of IA practices

Giulia Santangelo

<http://crie.jrc.ec.europa.eu>

**Centre for Research on
Impact Evaluation**
DG EMPL - DG JRC

CRIE

- ▶ Centre for **Research on Impact Evaluation**
 - ▶ Joint DG EMPL-DG JRC initiative, established in **June 2013**
- ▶ **Motto**
 - ▶ Support to MS and DG EMPL to set up the necessary arrangements for carrying out **Counterfactual Impact Evaluations (CIE)** of interventions funded by the European Social Fund (ESF)
- ▶ **Team**
 - ▶ Researchers with a background in **Economics** and Statistics
 - ▶ Experience in labour economics, theoretical and applied **econometrics, impact evaluation methods**
- ▶ **Why** did DG JRC and DG EMPL decide to put money and invest in this field?... I come back **later** on this

1. Talk: messages
2. Macroeconomic models
3. Counterfactual Impact Evaluations - CIE
4. A crash introduction to CIE methods

5. Randomised experiments
6. Quasi-experimental methods
7. Conclusion

Presentation Outline

2. Macroeconomic models
3. Counterfactual Impact Evaluations - CIE
4. A crash introduction to CIE methods
5. Randomised experiments
6. Quasi-experimental methods
7. Conclusion

The purpose of my talk

- ▶ Not really on **Ex-ante** Impact Assessment (IA)...more on **Ex-post** Impact Evaluation (CIE)
- ▶ However, we have a **common interest**: we want to know about the **Impact**
- ▶ Cross breeding of ideas useful

Key messages

- ▶ Ex-post CIE can be **used** for Ex-ante IA
- ▶ The use of Ex-post CIE for Ex-ante IA implies
 - ▶ Promotion of a **culture** of Evaluation
 - ▶ Staff in charge of IA to be **knowledgable** on CIE methods
- ▶ Ex-post CIE must be **planned well in advance** in the Ex-ante IA

Our common interest: Impact

- ▶ We need to **quantify** the **effect** of a policy
- ▶ **Why?** Evidence based policy making needed to
 - ▶ Improve the quality and **effectiveness** of public policies
 - ▶ Promote accountability
- ▶ **Quantitative** methods
 - ▶ Macroeconomic models
 - ▶ Impact evaluation based on counterfactuals
- ▶ ...Important to make the distinction between **Impact** and **Expected Impact**
- ▶ CIE is about **quantifying** the **impact** per se of a policy

1. Talk: messages
2. Macroeconomic models
3. Counterfactual Impact Evaluations - CIE
4. A crash introduction to CIE methods

5. Randomised experiments
6. Quasi-experimental methods
7. Conclusion

6. Quasi-experimental methods
7. Conclusion

Macroeconomic models

Pros

- ▶ Holistic representation of an economic system
- ▶ **Ex ante** and **ex post** evaluations: possible to evaluate the intended effect of the program at its design stage
- ▶ Possibility to test various scenarios

Cons

- ▶ **Theoretically** driven: modeler's perspective
 - ▶ Different models = different conclusions for a given policy
 - ▶ Calibration issue
- ▶ **Not causal** inference
- ▶ Complex for non experts

1. Talk: messages
2. Macroeconomic models
3. Counterfactual Impact Evaluations - CIE
4. A crash introduction to CIE methods

5. Randomised experiments
6. Quasi-experimental methods
7. Conclusion

CIE: one tool among others

- ▶ **Impact** evaluation: particular type of evaluation
 - ▶ Seek to answer **cause-and-effect** questions
- ▶ One tool among others
 - ▶ Must be associated with a **theory-based impact** evaluation
 - ▶ Must be complemented by **monitoring/process** evaluation

Ingredients for a counterfactual-based evaluation

- ▶ **Well defined** intervention targeted at a **well defined population**
 - ▶ Some units i are exposed to the policy intervention (**treated** unit) others are not (**untreated/control** units)

$$D_i = 1 \text{ if treated}$$

$$D_i = 0 \text{ if untreated}$$

- ▶ **Expected effect**: change of the outcome Y_i for the units i exposed to the intervention

$$Y_i = Y_{1i} \text{ if treated}$$

$$Y_i = Y_{0i} \text{ otherwise}$$

5. Randomised experiments
6. Quasi-experimental methods
7. Conclusion

What your dataset would look like

A screenshot of the Microsoft Excel interface. The ribbon shows the 'Home' tab with options for File, Home, Insert, Page Layout, Formulas, Data, Review, and View. The 'Font' section includes options for Cut, Copy, Paste, Format Painter, Calibri font, size 11, bold, italic, underline, and text color. The 'Alignment' section includes options for text alignment and merge & center. The 'Number' section includes options for currency, percentage, and decimal places. The active cell is E1. The spreadsheet contains a dataset with 18 rows and 8 columns (A-H).

	A	B	C	D	E	F	G	H
1	Y-Outcome	D-Treatment	age	Gender				
2	0	0	23	1				
3	1	0	48	0				
4	0	1	32	0				
5	1	0	48	0				
6	0	0	37	0				
7	0	0	23	0				
8	1	1	43	0				
9	0	0	45	0				
10	1	0	27	0				
11	1	1	51	0				
12	0	0	29	1				
13	1	1	33	0				
14	1	0	41	1				
15	0	0	34	1				
16	1	1	32	1				
17	1	0	42	0				
18	1	0	17	1				

Ingredients for a counterfactual-based evaluation

- ▶ The **treatment effect** for individual i is defined by $Y_{1i} - Y_{0i}$
- ▶ **Problem**: only one potential outcome is observed which implies that we cannot measure $Y_{1i} - Y_{0i}$
- ▶ **Consequence**: we must build a **counterfactual** to be able to estimate the impact of the treatment
 - ▶ **Counterfactual**: if we observe Y_{1i} in the treatment group, we need to **estimate** Y_{0i} , the “value of the outcome variable for individual i in the treatment group had it been assigned to the control group instead”

Counterfactual-based program evaluation

In Practice

- ▶ Treated units: average outcome $\text{ave}(Y_{1i})$
- ▶ Control units used for the counterfactual, average outcome $\widehat{\text{ave}}(Y_{0i})$
- ▶ **Impact** of the intervention: $\text{ave}(Y_{1i}) - \widehat{\text{ave}}(Y_{0i})$
- ▶ **Data**: it is necessary to have information on treated and untreated units (administrative data/surveys)

Counterfactual-based program evaluation

Pros and Cons

- ▶ Measure the **causal effect** of an intervention: crucial for informed policy dialogue
- ▶ Challenge: identifying a **convincing** counterfactual
- ▶ Examines **"the effect of the cause"** but does not explain "the causes of an effect"
- ▶ **After** program implementation
- ▶ Can be only applied to some specific specific policies/interventions

Corollary 1

- ▶ **Ex-post CIE** can be used for **Ex-ante IA**
 - ▶ When available, ex-post evaluations of similar or related policies should support the ex-ante evaluation process, and in particular help identifying the predicted impact(s) of the policy proposal under scrutiny (e.g logic of intervention)

Example

- ▶ Evaluation: **Do hospitals make people healthier?**
- ▶ The National Health Interview Survey (NHIS) includes the following 2 **questions**
 - ▶ “During the past 12 months, was the respondent a patient in a hospital overnight?” Can be used to identify recent **hospital visitors**.
 - ▶ “Would you say your health in general is excellent (1), very good (2), good (3), fair (4), poor (5)?”. Answers to this question define **health status** (1 = excellent health to 5 = poor health)
- ▶ **Impact** of hospitals? ... we might be tempted to **compare** the health status of those **who have been to the hospital** to the health of those **who have not been to the hospital**.

Results based on a naive counterfactual

Group	Sample Size	Mean health status	Std. Error
Hospital	7774	2.79	0.014
No Hospital	90049	2.07	0.003

- ▶ The difference in the means is **0.71**, a large and highly significant contrast in favor of the non-hospitalized.
- ▶ Taken at face value, this result suggests that going to the **hospital makes people sicker**.
- ▶ Are just hospitals full of other sick people who might infect us, and dangerous machines and chemicals that might hurt us?

Selection Bias

- ▶ Using individuals who were **not hospitalized** to measure the **counterfactual is wrong**
 - ▶ **Selection bias**: people who go to the hospital are probably less healthy to begin with. Moreover, even after hospitalization, people who have sought medical care are not as healthy, on average, as those who never get hospitalized in the first place (though they may well be better than they otherwise would have been).
- ▶ To measure the effect of the hospitalization, we need to find a good counterfactual, i.e. a proxy **for the health status of those hospitalized, had they not been hospitalized**

Corollary 2

- ▶ **Staff** need to be **trained** so as to understand how to read studies based on CIE and to judge about the "quality" of the counterfactual used for the estimation of the impact
- ▶ CIE is essentially based on **econometrics/statistics**
 - ▶ Quantitative background needed

Why CRIE?

- ▶ Coming back to the previous question: Why **CRIE**?
- ▶ DG EMPL's concern :
 - ▶ Difficult economic times: pressing need for the EU to demonstrate the **achievements** of the European Social Fund (ESF) and other financial instruments
 - ▶ 2014-2020 programming period: common and ESF-specific provisions: involve a shift toward **impact evaluation culture**
- ▶ **CRIE**: to develop a capacity in house on CIE and help DG EMPL and MS when it is question of quantifying the impact of an intervention.

5. Randomised experiments
6. Quasi-experimental methods
7. Conclusion

How to construct the counterfactual?

- ▶ **Experimental** approach
- ▶ **Quasi-experimental** methods
 - ▶ Difference in Differences (**DiD**)
 - ▶ Regression Discontinuity Design (**RDD**)
 - ▶ Propensity Score Matching (**PSM**)
 - ▶ Instrumental Variables (**IV**)
- ▶ Other methods exist

1. Talk: messages
2. Macroeconomic models

6. Quasi-experimental methods
7. Conclusion

Presentation Outline

1. Talk: messages
2. Macroeconomic models
3. Counterfactual Impact Evaluations - CIE
4. A crash introduction to CIE methods
- 5. Randomised experiments**
6. Quasi-experimental methods
7. Conclusion

Randomised experiments - the gold standard

- ▶ An essential objective of CIE methods is to identify situations where we can assume that the selection bias **does not exist** or find ways to **correct for it**
- ▶ Experimental approach = gold standard among CIE methods because the **randomisation solves the selection bias**
 - ▶ Since treatment and control groups are statistically equivalent, **differences in outcomes** between the groups can be attributed to the intervention.
 - ▶ Random assignment into treatment from the pool of experiment participants ensures that the treatment and control groups are **“statistically” equivalent**.

A graphical representation

Practical problems with experiments

► Ethical/legal issues

Randomised design can be politically unfeasible because it is hard to justify **discrimination** between individuals who can benefit and cannot, especially in poor areas.

Counter-arguments:

- **Uncertainty** about the results
- **Long-run** benefits for the society
- In the presence of limited resources, random assignment is **fair and transparent**
- Some **methods** of randomisation can **attenuate** these issues: "Randomized Promotion"

Job search assistance example

- ▶ Characteristics of the intervention
 - ▶ Job-search assistance and counseling.
 - ▶ Information is collected for $N = 400$ unemployed
 - ▶ Sampled individuals are randomly assigned to a treatment and control group.
 - ▶ Variable of interest Y is the change in income before-after (continuous).
- ▶ What we observe
 - ▶ Y_i , the change in log wage
 - ▶ $D_i = 1$ if in the job-search assistance intervention, otherwise $= 0$
 - ▶ $X_i = \text{age}_i$, in the range $[15,65]$

Example - perfect randomisation

$$Y_i = \alpha + \rho D_i + u_i$$

Y	Coef.	Std. Err.	t	P> t	[95% Conf. Interval]
D	.9044507	.0563235	16.06	0.000	.793722 1.015179
_cons	2.50767	.0281617	89.05	0.000	2.452305 2.563034

Example - perfect randomisation

$$H_0 : \text{ave}(\text{age}_i | D_i = 1) = \text{ave}(\text{age}_i | D_i = 0)$$

$$t = (\widehat{\text{ave}}(\text{age}_i | D_i = 1) - \widehat{\text{ave}}(\text{age}_i | D_i = 0)) / \sqrt{\left(\frac{\widehat{\text{var}}(\text{age}_i | D_i = 1)}{n_1} + \frac{\widehat{\text{var}}(\text{age}_i | D_i = 0)}{n_0} \right)} = 0.48$$

$|t| < 1.96$ implies H_0 cannot be rejected ($\alpha = 0.05$) \Rightarrow data supports perfect randomisation

3. Counterfactual Impact Evaluations - CIE
4. A crash introduction to CIE methods

5. Randomised experiments
6. Quasi-experimental methods
7. Conclusion

Presentation Outline

1. Talk: messages
2. Macroeconomic models
3. Counterfactual Impact Evaluations - CIE
4. A crash introduction to CIE methods
5. Randomised experiments
- 6. Quasi-experimental methods**
7. Conclusion

Quasi-experimental methods

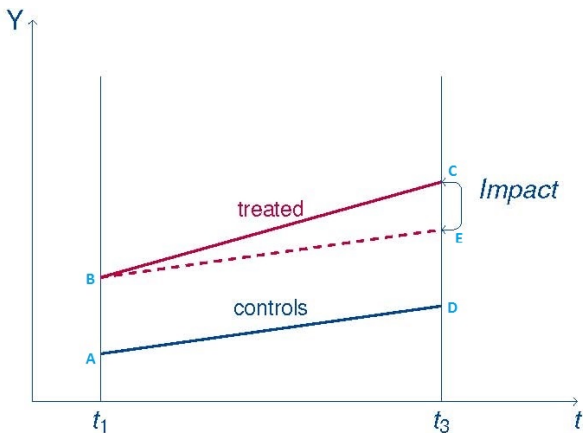

- ▶ When randomization not feasible, possibility to rely on statistical methods that attempt to **mimic** a randomization with the objective to **solve the selection bias issue**
 - ▶ From now on, participation to the program is not random. i.e., participation is based on some **criteria** or/and is **voluntary**
 - ▶ As a consequence, treated and controlled units differ along **observable and unobservable characteristics**: selection bias

Differences in differences

- ▶ Explore the time dimension of the data to define the counterfactual
 - ▶ Beneficiaries and non beneficiaries of the program are observed **before** and **after** the implementation of the policy

A graphical representation

Estimation

- ▶ The difference in the outcome variable **before and after treatment** in the **control** group is subtracted from the difference in outcome before and after treatment in the **treated** group

$$\textit{Impact} = [CD] - [AB]$$

- ▶ **Valid** if the counterfactual trend is identical for treated and non treated groups:**common trend assumption**

Example: firm-simulation class

- ▶ **Description.** A 1-year firm-simulation class is implemented on some bachelor students. The outcome variable is a score on a entrepreneurial attitude and skills standardized test.
- ▶ **Data.** We observe the score before and after the intervention for participants and non-participants along with some individual characteristics.
- ▶ **Impact.** What is the effect of the intervention on the entrepreneurial skills of participants? Do they increase or remain unchanged?

Results

Simple difference-in-differences

	Treatment status		Difference
	D=0; N=232	D=1; N=168	
Time t_1	4.58	5.57	0.99
Time t_3	8.61	22.42	13.81
Change $t_3 - t_1$	4.03	16.85	12.82

Check the common trend assumption: Graphical check

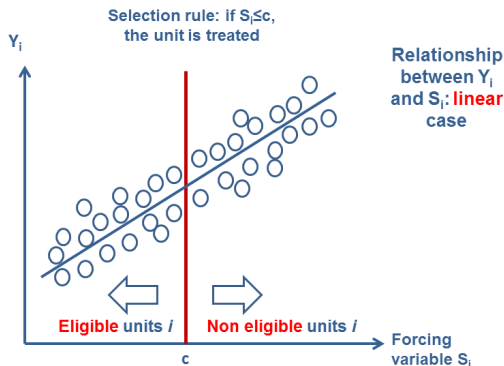

Regression Discontinuity Design

Eligibility for a program determined by a **rule** treatment assignment based on the value of a continuous variable S_i called the **forcing variable** : **Treatment**:

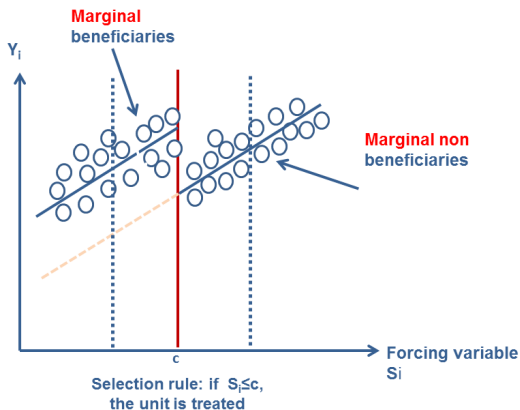

$$D_i = 1 \text{ if } S_i \leq c$$

$$D_i = 0 \text{ if } S_i > c$$

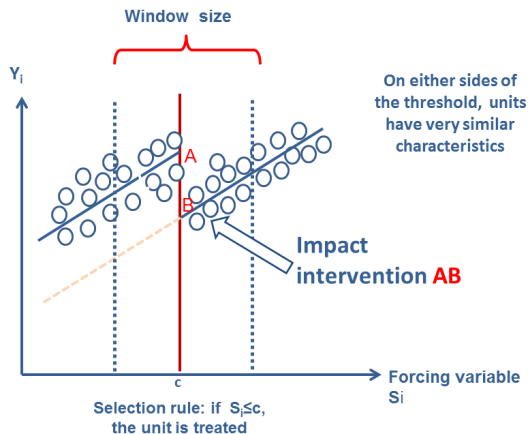

Without the intervention, linear case

After the intervention

Marginal beneficiaries and non beneficiaries

Impact in a snapshot

- ▶ **Eligibility rule:** On either sides of c , individuals have very **similar characteristics**, but some are treated and others are not
- ▶ **Counterfactual:** units above the cut-off who did not participate, i.e **marginal non beneficiaries**
- ▶ **Effect of the intervention:** **difference** in the average **performance** between **marginal beneficiaries** and **marginal non beneficiaries**

Example: Hunt-for-job support for non natives

Characteristics of the intervention

- ▶ To tackle unemployment among the non native population, unemployment offices in Spain put in place in 2010 hunt-for-job support.
- ▶ Only unemployed non-natives with a tertiary education, **aged 40 or less** can participate to this program.
- ▶ The duration of the support is 6 months.

Example: Hunt-for-job support for non natives

What we observe

- ▶ Y_i , the average difference in monthly log income between 2012 and 2010 at the individual level
- ▶ D_i , =1 if in the support program, =0 otherwise
- ▶ S_i , the forcing variable, i.e. the **age** of the individual
- ▶ $c = 40$

What we want to measure

- ▶ Impact of the intervention on Y_i

Graphic interpretation

Impact of the intervention corresponds to the jump in the value of Y_i at $c = 40$

Training intervention: estimation of the impact

Participating in the hunt-for-a job support **increases the monthly income by 66 percent**

Linear regression

Number of obs = 400
 F(3, 396) = 56.64
 Prob > F = 0.0000
 R-squared = 0.3122
 Root MSE = .47317

Y	Coef.	Robust Std. Err.	t	P> t	[95% Conf. Interval]	
D	.6634251	.0856094	7.75	0.000	.4951194	.8317309
age	.1181823	.0164631	7.18	0.000	.0858164	.1505482
age2	-.001377	.0001916	-7.19	0.000	-.0017536	-.0010004
_cons	-2.268112	.3747427	-6.05	0.000	-3.004846	-1.531378

Corollary 3

- ▶ Ex-post CIEs need to be **planned** well in advance
 - ▶ CIE necessitates specific **data arrangements** which should be outlined in the IA
 - ▶ Advanced planning is required in order to first identify and then collect data on outcome indicators but also contextual information on both the **treated** and **control** groups, before and after the policy intervention.
 - ▶ Impact evaluation is also **time and resource demanding**. This should be clearly spelled out in the IA.

4. A crash introduction to CIE methods

5. Randomised experiments
6. Quasi-experimental methods
7. Conclusion

Presentation Outline

1. Talk: messages
2. Macroeconomic models
3. Counterfactual Impact Evaluations - CIE
4. A crash introduction to CIE methods
5. Randomised experiments
6. Quasi-experimental methods
- 7. Conclusion**

Conclusion

- ▶ If you are interested in assessing the impact of EU policy:
CIE are useful, even for ex-ante IA
