Received: 11 November 2013 / Accepted: 22 December 2014

Abstract. The paper presents the newly developed dynamic spatial general equilibrium model of European Commission, RHOMOLO, and proposes its future extensions. The model incorporates several elements from economic geography in a novel and theoretically consistent way. It describes the location choice of different types of agents and captures the interplay between agglomeration and dispersion forces in determining the spatial equilibrium. The model is also dynamic as it allows for the accumulation of factors of production, human capital and technology. This makes RHOMOLO particularly suited for simulating policy scenario related to the EU cohesion policy and for the analysis of its impact on the regions and the Member States of the union.

1 Introduction

1.1 Need for an EU-wide model at the regional level

Cohesion Policy aims at fostering the economic and social development of the EU and its regions. Assessing impact of the policy at the macroeconomic level is therefore a key aspect

when gauging the expected impact of the policy (ex-ante evaluation) or the results it has delivered (ex-post evaluation).

The challenges to the evaluation of cohesion policy in the face of broadening objectives, thematic concentration and multi-level governance have been examined extensively in the literature, and in this journal in particular. Monfort (2012) provides an excellent overview in which he identifies three key methodological issues: (i) the need to bridge the gap between project-level and macroeconomic assessments of the returns to investment under cohesion policy; (ii) the lack of econometric evidence on the extent to which the availability of Structural Funds has had a positive impact on (the growth rates of) labour productivity and total factor productivity; and (iii) the failure to make the assumptions on which the design and implementation of the policy are based explicit.

The economic and financial crisis has put new strains on the financing of public investment in all Member States. This has led to greater scrutiny of the spending out of Structural and Cohesion Funds, which the Council of the European Union on the proposal of the Commission has moved forward as part of the European economic recovery plan. Within this context, Monfort (2012) points out that the typical growth regressions using regional data are severely biased and that a more structural approach focusing on the priorities for investment at the regional level, differentiated by economic starting point, is called for. This paper presents a structural modelling approach which allows empirical evidence on the returns to categories of investment to be taken explicitly into account.

In an attempt to address these challenges, this paper presents the newly developed dynamic spatial general equilibrium model – RHOMOLO – and proposes extensions, which includes the basic mechanisms through which agglomeration and dispersion occur and which allows the extent to which economic growth and employment in the regions is affected by public investment support to be simulated. In developing a dynamic spatial general equilibrium modelling framework and implementing it empirically for the whole EU at the regional level, our work attempts to fill the gap identified in the literature (Capello 2009). The model closest to RHOMOLO is CGEurope (Broecker and Korzhenevych 2013). Whereas CGEurope is more sophisticated along the spatial dimension, RHOMOLO provides greater sectoral detail. Each of the 267 NUTS 2 regional economies is divided into six (NACE1) economic sectors. In addition, RHOMOLO includes the labour market and in a currently being developed module also migration for different levels of skills. This makes it a comprehensive tool for assessing the impact assessment of the whole of cohesion policy at the regional level, which amounts to roughly 50 billion euro of spending via the EU budget per year.

1.2 Overview of the RHOMOLO model

The domestic economy of the RHOMOLO model (which corresponds to the EU) consists of $R$ regions $r = 1, \ldots, R$, which are included into $M$ countries $m = 1, \ldots, M$. Each region is inhabited by $H_r$ households which are immobile. They partly determine the size of the regional market. The income of households consists in labour revenue (wages), capital revenue and government transfers. It is used to consume final goods, pay taxes and accumulate savings.

The final goods sector includes $s = 1, \ldots, S$ different economic sectors in which firms operate under monopolistic competition à la Dixit and Stiglitz (1977). Each firm produces a
differentiated variety which is considered as an imperfect substitute to the other by households and firms. The number of firms in sector \( s \) and region \( r \) is denoted by \( N_{s,r} \). It is large enough so that strategic interactions between firms is negligible. Goods are either consumed by households or used by other firms as intermediate inputs or as investment goods. The number of firms in each region is endogenous and to a large extent determines the spatial distribution of economic activity.

The rest of the world is introduced in the model as a particular region (indexed by \( R \)) and particular sector (indexed by \( S \)). Sector \( S \) differs from domestic sectors in that it only has one variety which is exclusively produced in region \( R \). Formally, we have \( N_{S,r} = 0 \) and \( N_{s,R} = 0 \) for all \( r \) and \( s \), and \( N_{S,R} = 1 \). The foreign variety of final goods is used as the numeraire.

Trade between (and within) regions is costly, implying that the shipping of goods between (and within) regions entails transport costs which are assumed to be of the iceberg type, with \( \tau_{s,r,q} > 1 \) representing the quantity of sector’s \( s \) goods which needs to be sent from region \( r \) in order to have one unit arriving in region \( q \) (see for instance Krugman 1991). Transport costs are assumed to be identical across varieties but specific to sectors and trading partners. They are related to the distance separating regions \( r \) and \( q \) but can also depend on other factors, such as transport infrastructure or national borders. Finally, transport costs can be asymmetric (i.e. \( \tau_{s,r,q} \) may differ from \( \tau_{s,q,r} \)). They are also assumed to be positive within a given region (i.e. \( \tau_{s,r,r} \neq 1 \)) which captures, among others, the distance between customers and firms within the region.

The present paper proposes two important RHOMOLO extensions. First, description of technological change directly follows Romer (1990) and Jones (1995). In their production process, final goods firms use durable goods. Each variety of durable goods is produced by a specific (durable goods) firm and traded on a regional market whose structure is monopolistic competition. In order to start operating, each durable goods’ firm must acquire a design from a research sector which uses human capital and existing knowledge to produce new designs.

Second, the structure of the labour market is also monopolistic competition. Each household supplies a specific variety of low, medium and high skilled labour services to firms which are considered as imperfect substitutes to the ones offered by other households. Changing wages is assumed to be costly which introduces nominal wage rigidity in the model.4

Finally, in each country there is a public sector which levies taxes on consumption and on the income of local households. It provides public goods in the form of public capital which is necessary for the operation of firms. It also subsidizes the private sector, including the production of R&D and innovation, and influences the capacity of the educational system to produce human capital.

The detailed regional and sectoral dimensions of RHOMOLO implies that the number of (non-linear) equations to be solved simultaneously is relatively high. Therefore, in order to keep the model manageable from a computation point of view, its dynamics is kept relatively simple. Three types of factors (physical capital, human capital and knowledge capital) as well as three types of assets (equities, domestic government bonds and foreign bonds) are accumulated between periods. Agents are assumed to save a constant fraction of their income each period and

---

3 An alternative modelling approach of growth at the regional level has been taken in Capello and Varga (2013) and Capello et al. (2014).

4 Assuming monopolistic competition both on the goods and the labour markets is in line with models such as Blanchard and Kiyotaki (1987). Such specification allows to focus both on price and wage decisions and in particular to introduce nominal rigidities in the model. In addition, as underlined by Manning (2010), monopolistic competition is a very simple manner to capture the idea of thick labour markets, namely that the high density of workers raises productivity, thereby making large labour markets more attractive for firms. This enriches the the description of the economic geography in the mode.
to form their expectations based only on the current and past states of the economy. The dynamics of the model is then described as in a standard Solow model, that is, a sequence of static sub-models that are linked between periods by the laws of motion determining the time path of some key stock variables.

The model includes several agglomeration and dispersion forces determining the location choice of firms. Those include backward (firms prefer to have good access to output markets) and forward linkages (firms prefer to have good access to input markets) as well as Marshallian technological spill-over. Dispersion forces relate to competition on the goods market as well as competition for local labour.

This paper aims at presenting the theoretical specifications underlying RHOMOLO in order to document and clarify the main assumptions and micro-founded mechanisms it contains. Section 2 details the behaviour of households while Section 3 focuses on firms in the final goods sector. It also describes how the interplay between the R&D and the durable goods sector leads to technological progress. Section 4 is devoted to the public sector and explains how policy interventions are introduced in the model. Section 5 lays down the conditions to clear the product, labour and financial markets and Section 6 elaborates on the notion of spatial equilibrium in the model. Section 7 shows data and empirical implementation. Finally, Section 8 concludes.

2 Households

Households make decisions about consumption, savings and labour supply (see Figure 1). We propose that in an extended version of RHOMOLO each household supplies a differentiated variety of labour which contains a low, medium and high skilled component. Let $e = lo, me, hi$
denote the low, medium and high-skilled component respectively. Preference of households is represented by a utility function which is additively separable in consumption and leisure:

\[
U\left(C_{h,q}, \sum_{e=lo,me,hi} V(1-l_{h,e,q})\right) = \log(C_{h,q}) + \sum_{e=lo,me,hi} V(1-l_{h,e,q}),
\]

where \(C_{h,q}\) is the consumption of final goods by household \(h\) in region \(q\) and \(l_{h,e,q}\) is the labour of type \(e\) it supplies. We assume that the sub-utility with respect to leisure takes the form of a constant elasticity of substitution (CES) with a standard labour supply elasticity (\(\kappa\)) and a skill specific weight (\(\omega_e\)) on leisure in order to capture differences in participation to the labour market between skill groups. We have

\[
\sum_{e} V(1-l_{h,e,q}) = \sum_{e} \frac{\omega_e}{1-\kappa} (1-l_{h,e,q})^{1-\kappa}.
\]

The budget constraint of household \(h, q\) can be written as

\[
P^e_q C_{h,q} \leq (1-s)Y_{C_{h,q}},
\]

where \(P^e_q\) is the price of final goods in region \(q\), \(Y_{C_{h,q}}\) is disposable income and \(s\) is the constant saving rate which is common to all households.

Disposable income is the sum of labour and capital income net of wage adjustment cost plus government transfers net of taxes:

\[
Y_{C_{h,q}} = \sum_{e} (1-t_m^w)w_{h,e,q}l_{h,e,q} - \Gamma_w(w_{h,e,q}) + (1-t_m^w)KI_{h,q} + \frac{TR_{H,m}}{\sum_{r=1}^{H} H_r},
\]

where \(w_{h,e,q}\) is the wage paid to household \(h, q\) for its skill level \(e\), \(KI_{h,q}\) is capital income, and \(TR_{H,m}\) denotes government transfers to households in country \(m\). \(\Gamma_w(w_{h,e,q})\) denotes the wage adjustment cost (which can be introduced in an extended version of RHOMOLO).

Capital income corresponds to the returns linked to the holding of three different types of assets: equities (i.e. liability against the durable goods firms in the \(R-1\) regions of the domestic economy), domestic bonds (i.e., liability against the \(M\) governments of the domestic economy) and foreign bonds (i.e., liability against the rest of the world). Let \(B^{k,x,r}_{h,q}, B^{G,m}_{h,q}, B^{F}_{h,q}\) denote the stock of these assets held by the household respectively in firm \(v\) of region \(r\), in government bonds of country \(m\) and in foreign bonds. The associated returns are respectively \(r^{k,x,r}_v, r^{G,m}_m, r^F\). The holding of equities also gives right to a share of the durable goods firms profit. Finally, we assume that the firms in the final goods sector are also owned by households who share their profits. Capital income then reads

\[
KI_{h,q} = \sum_{r=1}^{H} \sum_{v=1}^{A_v} r_v^k B^{k,x,r}_{h,q} + \sum_{m=1}^{M} t_m^G B^{G,m}_{h,q} + r^F B^F_{h,q} + \sum_{r=1}^{H} \sum_{v=1}^{A_v} s_{h,q} B^{k,x,r}_{h,q} \pi_{v,r} + \frac{1}{H} \pi^{FG},
\]

where \(A_v\) is the number of durable goods firms in region \(r\), \(\pi_{v,r}\) is the profit of the durable goods firm \(v\) in region \(r\), \(H = \sum_{r=1}^{R-1} H_r\) is the domestic population and \(\pi^{FG}\) is the sum of profits of the final goods sector. \(s_{h,q}^{k,x,r} = B^{k,x,r}_{h,q} / a_{v,r}\) is the share of total assets issued by firm \(v, r\) (\(a_{v,r}\)) held by the household. Except for \(H\), these variables are endogenous and their determination is described in the following sections of the paper.
We propose that in an extended version of RHOMOLO wages are subject to convex adjustment cost:

\[ \Gamma_{w}(w_{h,x,q}) = \sum_{e} \gamma_{e} l_{h,x,q} w_{h,x,q} \]

The optimization problem of the household is solved by maximizing the associated Lagrangian

\[ L = C_{h,q} + \sum_{e} \frac{\omega_{e}}{1 - \kappa} (1 - l_{h,x,q})^{1 - \kappa} - \lambda (P_{c} C_{h,q} - (1 - s)Y_{h,q}) \]

with respect to consumption, \( C_{h,q} \), and labour supply, \( l_{h,x,q} \).

2.1 Consumption

First order conditions to that optimization problem imply that the aggregate consumption level is directly related to disposable income:

\[ C_{h,q} = \frac{(1 - s)Y_{C,h,q}}{P_{c}}. \]

Households consume all varieties of final goods available in the economy. In order to represent love for varieties, \( C_{h,q} \) is assumed to take the form of a CES sub-utility function defined as:

\[ C_{h,q} = \left( \sum_{i=1}^{R} \sum_{s=1}^{S} \sum_{r=1}^{N_{e}} (c_{h,q}^{i,s,r})^{\theta} \right)^{1/\theta} \]

where \( c_{h,q}^{i,s,r} \) is the consumption of variety \( i \) of sector \( s \) produced in regions \( r \) and \( \beta_{s} \) is the weight given to sector \( s \) in the household’s preference.

Household \( h, q \) chooses a consumption bundle in order to maximize (4) subject to the following constraint:

\[ \sum_{i=1}^{R} \sum_{s=1}^{S} \sum_{r=1}^{N_{e}} t_{s,r,q} (1 + t_{s,m}^{c}) p_{i,e,q} c_{h,q}^{i,s,r} = (1 - s)Y_{C,h,q} \]

where \( p_{i,e,q} \) is the price of variety \( i, s, r \), \( t_{s,r,q} \) is trade cost from region \( r \) to region \( q \), and \( t_{s,m}^{c} \) is the tax rate applied to consumption of sector \( s \) goods in country \( m \) (where region \( q \) is assumed to be located).

The price of variety \( S, R \) produced in the rest of the world is assumed to be exogenous to the domestic economy, namely, \( P_{S,R} = \bar{P}_{S,R} \). We also assume that foreign households have the same type of preference regarding domestic goods and that the share of their disposable income devoted to the consumption of domestic goods is fixed.

5 Distribution parameters are introduced in the CES in order to calibrate the model (see for instance Anderson and van Wincoop 2003 or Balistreri et al. 2011). These parameters are not included here for the sake of simplicity.

6 The model as coded incorporates a nested CES utility function to allow for different elasticities of substitution between varieties of a given sector on the one hand and sectors on the other hand. This feature is not introduced here to simplify notations.
Solving this problem leads to the following demand for variety \( i, s, r \):

\[
C_{h,q}^{i_s} = \left( \frac{\tau_{s,r,q} (1 + r_{s,m} p_{i,s,r})}{\beta_s p_q^e} \right)^{\frac{1}{\theta-1}} \frac{(1-s)Y C_{h,q}}{p_q^e},
\]

where \( p_q^e \) is the following CES price index:

\[
p_q^e = \left( \sum_{i=1}^{R} \sum_{s=1}^{S} \sum_{r=1}^{N_{i,r}} \beta_s^{1-\theta} (\tau_{s,r,q} (1 + r_{s,m} p_{i,s,r}) )^{\theta-1} \right). \tag{6}
\]

According to (5), demand for variety \( i, s, r \) is a fraction of real income spent on final goods. This fraction decreases with the relative price of this variety, the relevant transport cost and tax rate, while it increases with relative preference for sector \( s \).

### 2.2 Labour supply

Each household decides which fraction of its time endowment will be devoted to leisure on the one hand and to labour in each types of skill on the other hand. We propose that in an extended version of RHOMOLO labour markets are characterized by monopolistic competition where, within each skill group, labour supplied by a particular household corresponds to a variety which is an imperfect substitute to the others. Maximizing (3) with respect to \( l_{h,e,q} \), we obtain the following wage setting rule:

\[
\frac{\omega (1-l_{h,e,q})^{-\frac{1}{\eta}}} = \frac{(1-t_m)^{w_{h,e,q}}}{p_q^e}, \tag{7}
\]

with

\[
\eta = \left[ \sigma(1-s) - \frac{\gamma_w (\sigma - 1) \pi^{w_{h,e,q}}}{(1-t_m)} \right].
\]

The real wage is set as a mark-up, \( \frac{1}{\eta} \), over the reservation wage (i.e., the marginal utility of leisure divided by the marginal utility of consumption). The mark-up depends on the substitutability between the different varieties of labour in the firms production function, \( \sigma \) (see below). Because adjusting wages is costly, the mark-up also depends on the level of wage inflation, \( \pi^{w_{h,e,q}} = \Delta w_{h,e,q}/w_{h,e,q} \), which implies that wages only adjust slowly to variation in prices.

We propose that in an extended version of RHOMOLO the household accumulates skill specific human capital, \( b_{h,e,q} \), according to

\[
\Delta b_{h,e,q} = b_{h,e,q} (e_{h,e,q} - 1) - \delta_{hc} b_{h,e,q}, \tag{8}
\]

allowing to offer \( b_{h,e,q} \) efficiency units. \( \Lambda \) represents the amount of time a household spends on education while \( \delta_{hc} \) is the depreciation rate for human capital.

### 3 Firms

#### 3.1 Final goods firms

Final goods firms produce horizontally differentiated varieties of final goods (see Figure 2). The final goods sector is characterized by monopolistic competition. It includes \( S \) sectors in which
each firm produces a variety which is an imperfect substitute to the others. The production function for firms is of the Leontieff type. The arguments are the quantities of intermediate inputs bought from all sectors and a Cobb-Douglas aggregate of the factors used in the production process, namely, labour and durable goods:

$$X_{i,s,r} = \min \{ y_{i,s,r}, a_1 X_{i,s,r}^1, \ldots, a_u X_{i,s,r}^u, \ldots, a_S X_{i,s,r}^S \} - FC_{i,s,r} + Sub_{i,s,r} + Sub_{i,s,r}^{EU},$$

where $X_{i,s,r}$ is the quantity produced by the firm producing variety $i$ of sector $s$ located in region $r$, $y_{i,s,r}$ is its value added, $X_{i,s,r}^u$ is an index of the intermediate inputs from sector $u$ and $a_u$ is the associated technical coefficient, assumed to be common to all firms in sector $s$ in country $m$, independently of their location within the country. The index $X_{i,s,r}^u$ is a CES aggregate of varieties produced in sector $u$:

$$X_{i,s,r}^u = \left( \sum_{q=1}^{N_u} \sum_{j=1}^{N_{i,s,r}} (x_{i,s,r}^{j,q})^{\frac{1}{\theta}} \right)^{\frac{1}{\theta}},$$

with $\theta \in (0, 1)$.

The firm’s value added is a Cobb-Douglas of the two factors used in the production process:

$$y_{i,s,r} = Z_{i,s,r} a_t L_{i,s,r}^{1-a_t} K C_{i,s,r}^{a_t},$$

Fig. 2. Firms and production structure in the RHOMOLO model: Final goods’ firms, national R&D firms and durable goods’ firms.
where $Z_{i,s,r}$ and $L_{i,s,r}$ are CES aggregates of the varieties of durable goods and of the various types of labour – low, medium and high-skilled – used by the firm.\(^7\) Let $KG_r$ denote the stock of public capital available in region $r$ which is assumed to affect positively total factor productivity.\(^8\) The firm also supports a fixed cost, $FC_{i,s,r}$. Finally, it benefits from subsidies of the national government ($Sub_{isr}^{m}$) and of the EU ($Sub_{isr}^{EU}$).

We propose that in an extended version of RHOMOLO durable goods and labour are assumed to be spatially immobile which implies that firms in regions $r$ can only obtain those two factors on the local market. Moreover, we propose that durable goods are not subject to internal transport costs (i.e. $\tau_{Z,s,r} = 1$). The respective CES indices read

$$Z_{i,s,r} = \left( \sum_{v=1}^{V} (z_{i,s,r}^{v})^{\rho} \right)^{1/\rho},$$

$$L_{i,s,r} = \left( \sum_{v=0}^{V} \sum_{h=0}^{H} (b_{i,s,r}^{h,v})^{\sigma} \right)^{1/\sigma},$$

where $\rho, \sigma \in (0, 1)$.

Profit maximization leads the firm to set the output price as a mark-up over marginal cost, where the mark-up depends on the elasticity of the total demand it faces. This includes demand from households, from other firms for intermediate inputs, from durable goods firms for investment goods and from the government. Given our assumptions concerning the preferences of these agents and the CES aggregates for intermediate inputs and for physical capital (see below), the elasticity of total demand is $1/(\theta - 1)$ and the price-making rule is

$$p_{i,s,r} = \frac{MC_{i,s,r}}{\theta}. \hspace{1cm} (11)$$

The marginal cost includes the cost of production factors and the cost of intermediate inputs:

$$MC_{i,s,r} = P_{i,s,r}^{y} + \sum_{u=1}^{S} P_{i,s,r}^{u} \alpha_{i,s,r}^{u},$$

where $P_{i,s,r}^{y}$ is the price of value added. Given the specification adopted for valued added, $P_{i,s,r}^{y}$ is common to all firms in sector $s$ and region $r$ and corresponds to a Cobb-Douglas of the factors’ price:

$$P_{i,s,r}^{y} = KG_r^{-\alpha_s} \left( \frac{P_{i,s,r}^{z}}{\alpha_s} \right)^{\alpha_s} \left( \frac{W_{i,s,r}}{1-\alpha_s} \right)^{1-\alpha_s}.$$

$P_{i,s,r}^{u}$, $P_{i,s,r}^{z}$ and $W_{i,s,r}$ are the price indices corresponding to the CES aggregates respectively of intermediate inputs, durable goods and labour varieties.

---

\(^7\) The firm uses effective units of labour which includes both physical units of labour and the associated human capital.

\(^8\) Note that according to this specification, each firm can benefit from the whole stock of public capital available in the region where it is located. This reflects the public good nature of public capital and in particular that it is non-rivalrous. We also assume it is non-excludable in that its use by firms does not incur direct payment but only indirect ones (the provision of pubic capital is financed by taxes) which are not internalized by the firm.
\[ P_{i,s,r}^u = \left( \sum_{q=1}^{N_q} \sum_{j=1}^{N_u} \left( t_{u,q,r} p_{j,u,q} \right) \right)^{\frac{\theta^{-1}}{\theta}} \] (12)

\[ P_{i,s,r}^z = \left( \sum_{v=1}^{N_v} p_{v,s,r}^z \right)^{\frac{1}{\rho^{-1}}} \] (13)

\[ W_{i,s,r} = \left( \sum_{e=0}^{1} \sum_{h=1}^{N_h} \left( b_{h,e,r}^\sigma w_{h,e,r}^\sigma \right) \right)^{\frac{1}{\sigma^{-1}}} \] (14)

where \( p_{j,u,q} \) is the price of variety \( j, u, q \) of final goods, \( p_{v,s,r}^z \) is the price of variety \( v, r \) of durable goods and \( w_{h,e,r} \) is the wage of household \( h, r \) for his labour service of skill \( e \).

We assume symmetry across firms (resp. households) in terms of the technology (resp. preferences) which implies that the price (resp. wage) set by each firm (resp. household) within one given region is the same. Accordingly, one easily verifies that \( P_{i,s,r}^u = P_u^s \) for all \( i, s \), \( P_{i,s,r}^z = P_z^s \) for all \( i, s, W_{i,s,r} = W, \) for all \( i, s, \) and \( P_{i,s,r}^y = P_y^s \) for all \( i \). Note that we also that consumption taxes do not apply to intermediate inputs.

The demand of the firm for each variety of intermediate inputs, durable goods and labour then take the following form, respectively:

\[ x_{i,s,r}^{l,u,q} = \left( \frac{t_{u,q,r} p_{j,u,q}}{p_u^s} \right)^{\frac{1}{\theta^{-1}}} x_{i,s,r}^u, \] (15)

\[ z_{i,s,r}^{l,v,r} = \left( \frac{p_{v,s,r}}{p_z^s} \right)^{\frac{1}{\rho^{-1}}} z_{i,s,r}, \] (16)

\[ l_{i,s,r}^{h,e,r} = \left( \frac{w_{h,e,r}^\sigma W^\sigma}{b_{h,e,r}^\sigma} \right)^{\frac{1}{\sigma^{-1}}} l_{i,s,r}. \] (17)

3.2 National R&D sectors

In this section we propose an extension of the current version of RHOMOLO. We assume that there are \( M \) national R&D sectors which produce new designs \( \Delta J_m \) using all varieties of skilled labour available on the national labour market (see Figure 2). The production process features learning by doing, as labour productivity is positively related to the pre-existing stock of designs. There are international technological spill-overs in the sense that the national R&D sector absorbs part of the technology produced within the \( M \) countries. Finally, the R&D sector is supported by the national government and the EU which provide subsidies, \( Sub_{RD}^m \) and \( Sub_{EU}^RD \), proportional to the production of new designs. Following Romer (1990) and Jones (1995), the production function of the R&D sector of country \( m \) reads

\[ P_{J,m} = J^w J^z \cdot W_{RD,m} - Sub_{RD}^m - Sub_{EU,m}^RD, \]

where \( J^w \) is the stock of design in the \( M \) economies and \( L_{RD,m} \) is a CES aggregate of the national skilled labour varieties.
Finally, designs are assumed to become obsolete after one period (i.e., the depreciation rate on designs is set to 1) which implies that firms must renew their licences every year to continue using the updated versions of the designs.\footnote{In fact, this assumption is adopted in order to avoid introducing inter-temporal decisions in the model and hence keep the description of its dynamics simple.}

\[ \Delta J_m = \left( \Omega \frac{P_{J,m} + \text{Sub}^R_{\text{R&D}} + \text{Sub}^R_{\text{EU}}}{W_{\text{R&D},m}} \right)^{1-\epsilon}, \]

where \( P_{J,m} \) is the price of new designs and \( W_{\text{R&D},m} \) is the CES wage index for the R&D sector:

\[ W_{\text{R&D},m} = \left( \sum_{r=1}^{R_m} \sum_{h=1}^{H_r} \left( b_{h,hi,r} W_{h,hi,r} W_{\text{R&D},m}^{\sigma} \right)^{\frac{1-\sigma}{\sigma}} \right)^{\frac{1}{\sigma-1}}. \]

Note that given the constant return to scale technology of the R&D sector, the average cost corresponds to the marginal cost and there is no profit at equilibrium, even in the short run. Moreover, as we assumed that new designs were only used for one period, the R&D sector does not benefit from rents or royalties.

The demand of the R&D sector for each variety of highly skilled labour from region \( q \) then takes the following form:

\[ l_{h,hi,r}^{\text{R&D}} = \left( \frac{W_{h,hi,r}}{b_{h,hi,r} W_{\text{R&D},m}^{\sigma}} \right)^{\frac{1}{\sigma-1}} L_{\text{R&D},m}. \quad (18) \]

### 3.3 Durable goods firms

As in section 3.2, in this section we propose an extension of the current version of RHOMOLO. We assume that durable goods firms use the output of national R&D firms and supply inputs to final goods firms (see Figure 2). In order to start operating, the firm \( v \) in the durable goods sector of region \( r \) must acquire one design and transform it into a new production process. The firm can only obtain designs from its national R&D sector by buying a licence which must be renewed each period. Production also entails a fixed cost denoted by \( FC_{v,r} \). Finally, the firm receives subsidies from the national government \( \text{Sub}_{\text{m},r} \) and of the EU \( \text{Sub}^{\text{EU},r} \). It operates under monopolistic competition and produces one variety of durable goods using physical capital. The production function is:

\[ z_{v,r} = K_{v,r}. \quad (19) \]

Capital is financed by selling assets \( a_{v,r} \) to households on the \( M \) national financial markets, which implies that \( a_{v,r} = P_k^v K_{v,r} \), with \( P_k^v \) being the price of physical capital. Asset \( a_{v,r} \) yields a gross return \( \rho_{v,r}^K P_k^v \) which corresponds to the rental price for one unit of capital. We assume capital to depreciate at a rate \( \delta_K \). This in fact corresponds to the mobile capital framework of
Martin and Rogers (1995) which assumes that (i) capital is mobile between regions and (ii) the revenue of capital is repatriated to the owner’s region.

Each unit of capital is a CES aggregate of varieties of final goods bought in all regions:

\[ K_{v,r} = \left( \sum_{q=1}^{R} \sum_{s=1}^{S} \sum_{i=1}^{N_{q,r}} K_{v,r}^{i,s,q} \right)^{\frac{1}{\theta}}. \]  

This index is equivalent to the one representing preferences of households which implies that price of capital is equal to the consumer price index, i.e. \( P_{v}^{k} = P_{c}^{v} \). Importantly, note that the price of capital is region-specific. This reflects the fact that varieties constituting physical capital must partly be imported. Given the existence of transport cost, physical capital is more costly in small/peripheral regions.

Transforming designs into an effective new production process is uncertain. We denote the probability to succeed in using a new design by \( \phi \). In order to capture the empirically well-documented fact that the capacity of a region to innovate depends on its technological level and the skills embodied in its human capital (see for instance Kancs and Ciaian 2011), we assume that \( \phi \) depends on the existing stock of operational processes which also corresponds to the number of durable goods firms, \( A_{r} \), and its stock of human capital, \( HC_{r} \):

\[ \phi_{r} = \left( \frac{A_{r}}{\sum_{r=1}^{R} A_{r}} \right) \left( \frac{HC_{r}}{\sum_{r=1}^{R} HC_{r}} \right)^{1-v}. \]  

The regional stock of human capital is defined as the number of effective units of high skilled labour available in region \( r \), i.e \( HC_{r} = \sum_{h=1}^{H} b_{h,hi} J_{h,hi,r} \).

The expected profit of the durable goods firm then reads

\[ \pi_{v,r} = \phi_{r} \left[ p_{v,r} z_{v,r} - r^{k}_{v,r} P_{c}^{v} K_{v,r} - P_{c}^{v} - FC_{v,r} + Sub_{m}^{v,r} + Sub_{E}^{v,r} \right]. \]  

Profit maximisation under the constraint (19) leads the durable goods firm to address the following demand for each variety of final goods:

\[ k_{v,r}^{i,s,q} = \left( \frac{\tau_{v,r} (1 + \tau_{m}) p_{i,s,q}}{\beta \cdot P_{c}^{v}} \right)^{\frac{1}{\theta-1}} K_{v,r}. \]  

The firm also sets its price as a mark-up over marginal cost with

\[ p_{v,r} = \frac{MC_{v,r}}{\rho}, \]  

where \( MC_{v,r} = r^{k}_{v,r} P_{c}^{v} \). This implies that production of the durable goods firm and hence its demand for capital depends negatively on the rental price of capital and positively on the demand addressed to the firm (accelerator mechanism). Investment corresponds to the variation in the stock of capital plus depreciation:

\[ I_{v,r} = \Delta K_{v,r} + \delta K_{v,r}. \]  

It is financed by the issuance of new assets, namely, \( P_{c}^{v} I_{v,r} = \Delta a_{v,r} \).
Note that, given the form of the production function (19) adopted for the durable goods sector, the production function of a final goods firm reads

\[ y_{i,s,r} = A_r^{1,1,1} K_r^{1,1,1} L_r^{1-\alpha_r} KG_{r}^{\theta_r} - FC_{i,s,r}, \] (25)

that is, the volume of output depends on the use of capital (embodied in the durable goods) and labour. As in Romer (1990), it also depends on technological change which takes the form of an increase in the range of durable goods the firms have access to. This range is endogenous and determined by the market conditions faced by durable goods firms, among which the number of final goods firms on the regional market and the performance of the national R&D sector.

4 Public sector

4.1 Government

We assume a multi-level governance framework where the national government interacts with the EU level. The expenditure of the national government of country \( m \) consists in consumption of final goods \( GC_m \), transfers to households \( TRH_m \), subsidies to firms \( Sub_m \), and government investment \( GI_m \). These components of government expenditure are all assumed to be fixed at exogenous levels, although they can serve as variables for modelling policy shocks.

Let \( G_m \) denote the sum of government consumption and investment. We assume government consumption and investment to be distributed among the regions of country \( m \) according to the shares of the population. The regional government also receives resources from the EU which we denote by \( TREU_q \). The amount of public consumption and investment taking place in region \( q \) (assumed to be in country \( m \)) then reads\(^{10}\)

\[ G_q = \frac{H_q}{H_m} G_m + TREU_q. \]

Analogously to households and firms, the regional governments have CES preference defined over the set of varieties produced in the domestic economy and abroad. We have

\[ G_q = \left( \sum_{r=1}^{R} \sum_{s=1}^{S} \sum_{i=1}^{N_{i,r}} \left( c_{G,q}^{i,s,r} \right)^{1/\theta} \right)^{1/\theta}. \]

The demand addressed by the public sector of region \( q \) to firm \( i, s, r \) is then

\[ c_{G,q}^{i,s,r} = \left( \frac{\tau_{s,r,q} (1 + t_{r,m}) p_{i,s,r}}{\beta_{s,i} p_{q}^{c}} \right)^{1/(\theta - 1)} G_q. \] (26)

The government contributes to the EU budget and in particular to cohesion policy funding, \( CPF \), proportionally to its weight in the EU GDP:

\[ TR_{m,EU} = \frac{GDP_{m}}{GDP} CPF, \]

\(^{10}\) Note that by limiting public consumption and investment in a given region to the allocation of resources received from the central government and the EU, we rule out the possibility for regional governments to finance their expenditure by raising their own taxes or issuing their own debt.
where \( GDP_m = \sum_{r=1}^{R_m} GDP_r \) and \( GDP = \sum_r GDP_r \). \( GDP_r \) is GDP of region \( r \) and is defined in the next section.

The government levies taxes on consumption as well as on capital and labour income which constitutes its revenues:

\[
T_m = \sum_{q=1}^{R_m} H_q \sum_{r=1}^{R} \sum_{s=1}^{S} t_{s,m} N_{s,r} p_{i,s,r} \tau_{i,s,r} x_{i,s,r} + \tau_m \left( \sum_{q=1}^{R_m} \sum_{s=lo,me,hi} H_s w_{h,s,r} I_{h,s,q} \right) + \tau_m \sum_{q=1}^{R_m} H_q K I_{h,q}.
\]

The public deficit in country \( m \) is the difference between government expenditure, including interests on the outstanding debt, and revenue:

\[
D_m = \sum_{q=1}^{R_m} P_{q} G_{q} + TR_{H,m} + TR_{m,EU} + r_m B_{G,m} + Sub_m - T_m - \sum_{q=1}^{R_m} TR_{EU,q},
\]

where \( B_{G,m} \) and \( Sub_m \) are respectively the public debt and government subsidies in country \( m \), with

\[
Sub_m = \sum_{r=1}^{R} \sum_{s=1}^{S} N_{s,r} Sub^b_{s,r} + Sub^{R&D}_{m} + \sum_{r=1}^{R_m} A Sub^{c,r}_{EU},
\]

Finally, the stock of public capital in region \( q \) increases with the level of public investment of the regional government and decreases with depreciation:

\[
\Delta KG_q = GI_q - \delta_k KG_q.
\]

4.2 Modelling policy intervention

In order to model the European cohesion policy (ECP) interventions, we regroup the different ECP expenditure categories into five broader groups of policy instruments (see Table 1). R&D related policy measures are modelled as subsidies (\( Sub^{R&D}_{EU,q} \)) reducing fixed costs in the R&D sector. Policy instruments aimed at increasing human capital are modelled as an education investment in skill-specific human capital, \( \Lambda_e \) and increases public consumption in the regions benefiting from the intervention. Transport infrastructure investments are modelled as a reduction of trade costs, \( \tau_{s,r,q} \). Other infrastructure investments are implemented in RHOMOLO as an increase of the stock of public capital, \( KG_r \). These interventions also increase the level of public consumption. ECP policy measure affecting particular industries or services are modelled as government subsidies reducing fixed costs in the final goods and/or in the durable goods sector (\( Sub^{FG}_{EU,q} \) and \( Sub^{z}_{EU,q} \)). Finally, technical assistance is assumed to increase government consumption.

In order to translate the impact of a particular policy measure on the model variables, we make use when relevant of complementary models or employ estimates from the literature. For example, in order to simulate the TEN-T investments in transport infrastructure, the improvements in the transport network due to transport infrastructure investments are first simulated with the transport model TRANSTOOLS, where the units of measurement are kilometres of new infrastructure, number of additional lanes, maximum speed, etc. In a

\[11\] This formulation does not prejudge how subsidies change with the number of firms. According to the policy scenario envisaged, the total amount of subsidies could increase/remain constant with the number of firms while subsidies allocated to individual firms remain constant/decrease with the number of firms.
second step, the impact of the changes in the accessibility of regions on economic variables is simulated with RHOMOLO, where the units of measurement are relative prices, wages, employment, GDP, etc.

In addition to supply-side effects, the ECP interventions have also demand-side effects (listed in Table 1). Both the demand and supply side effects together with the induced general equilibrium effects determine the net policy impact and hence all are important for policy incidence. The demand-side effects are implemented as additional government expenditure of final demand and investments goods.

## 5 Market equilibrium and closure rules

### 5.1 Goods, labour and innovation markets

All households and all firms within a given sector are assumed to be symmetric, which implies that in a specific regions \( r \) wages and quantities consumed are identical for all households while prices and quantities produced are identical for all firms.

The firm \( i, s, r \) faces demand from four types of agents: households (domestic and foreign) \( D_H^{i,s,r} \), firms of the final goods sector \( D_F^{i,s,r} \), firms of the durable goods sector \( D_K^{i,s,r} \) and the domestic public sector \( D_G^{i,s,r} \):

\[
D_H^{i,s,r} = \sum_{q=1}^{R} H_q e_{i,s,r}^{h,q},
\]

\[
D_F^{i,s,r} = \sum_{u=1}^{S} \sum_{q=1}^{R} N_u \lambda_{i,s,r} q^{j,u,q},
\]

\[
D_K^{i,s,r} = \sum_{q=1}^{R-1} A_q k_{i,s,r} q^{j,q},
\]

\[
D_G^{i,s,r} = \sum_{q=1}^{R-1} C_{G,q} q^{l,q},
\]

Notes: The presented policy interventions are illustrative. Many more policy instruments and their combinations can be implemented in RHOMOLO.
where \( c_{i,j,q}^{s,r}, x_{i,j,q}^{s,r}, k_{i,q}^{s,r} \) and \( c_{i,q}^{s,r} \) are respectively given by Equations (5), (15), (23) and (26). The four components of total demand feature the same price elasticity and the firm sets its price, \( p_{i,s,r} \), according to the rule given by Equation (11), thereby equating demand and supply:

\[
X_{i,s,r} = D_{H}^{s,r} + D_{P}^{s,r} + D_{K}^{s,r} + D_{G}^{s,r}.
\]

GDP of region \( r \) then corresponds to

\[
\sum_{s=1}^{S} N_{i,s,r} \cdot P_{i,s,r} \cdot y_{i,s,r} = \sum_{s=1}^{S} N_{i,s,r} \cdot P_{i,s,r}^{y} \cdot X_{i,s,r}.
\]

In region \( q \), \( H_{q} \) different varieties of low, medium and high skilled labour are supplied on the labour market. Labour supply of skill level \( e \) by on household \( h \) in region \( q \), denoted as \( l_{h,e,q}^{s} \) is given by Equation (7).

Labour demand stems from the final goods sector on the one hand and from the national R&D sector on the other hand. Labour demand from the final sector is obtained by aggregating individual firms demand for for labour of skill level \( e \) and variety \( h \), denoted by \( l_{i,s,q}^{h,e} \), is given by Equation (17). Labour demand from the national R&D sector for highly skilled labour of variety \( h \) from region \( q \) is denoted by \( l_{R&D}^{h,q} \) and given by Equation (18).

Prices and quantities adjust so as to obtain equilibrium on the labour market, that is:

\[
l_{h,e,q} = \sum_{i=1}^{N_{q}} \sum_{j=1}^{S} l_{i,s,q}^{h,e} \quad \text{for } e = lo, me,
\]

\[
l_{h,h,q} = \sum_{i=1}^{N_{q}} \sum_{j=1}^{S} l_{i,s,q}^{h,h} + l_{R&D}^{h,q}.
\]

On the market for durable goods of region \( r \), the firm \( v \) faces the following demand:

\[
D_{F}^{v,r} = \sum_{i=1}^{S} N_{i,s,r} \cdot z_{i,s,r}^{v,r}
\]

where \( z_{i,s,r}^{v,r} \) is specified by Equation (16). The price setting rule (24) ensures that supply equals demand so that

\[
z_{i,s,r}^{v,r} = D_{F}^{v,r}.
\]

Finally, the demand for designs addressed to the R&D sector corresponds to the number of firms willing to operate in the durable goods sector \( \sum_{r=1}^{R} N_{r}^{v} \). As described in the next section, this number depends on the price of designs, \( P_{J,m} \), so that at equilibrium we have

\[
J_{m}^{v} = \sum_{r=1}^{R} \frac{A_{r}}{\phi_{r}}.
\]

5.2 Financial markets

We select a saving driven closure rule where private saving is determined as a constant fraction of households’ income (see Equation 1). At equilibrium: (i) private saving must finance private investment, public deficits and the deficit of the trade balance; and (ii) returns on the three types
of assets held by households must be equal. Finally, we assume that financial markets are fully integrated at the level of the \( m \) countries.

Private investment in region \( r \) is the sum of investment of firms of the durable goods sector (i.e. the firms directly using capital as a production factor): \( P^C I_r = \sum_{v=1}^N A_r P^C I_{v,r} \).

The trade balance deficit of each country \( (TB_m) \) corresponds to the value of its exports minus the value of its imports, \( TB_m = X_m - M_m \) where:

\[
X_m = \sum_{r=1}^{R} \sum_{v=1}^{N} \tau_{S,v,r} P_{S,v} C_{v,r},
\]

\[
M_m = \sum_{r=1}^{R} \sum_{h=1}^{H} \tau_{S,R,r} P_{S,R} C_{h,r}.
\]

The trade balance of the domestic economy then corresponds to the sum of the national trade balances with respect to the rest of the world:

\[
TB = \sum_{m=1}^{M} TB_m.
\]

We therefore have

\[
S = \sum_{r=1}^{R-1} \sum_{h=1}^{H} S_{h,r} = \sum_{r=1}^{R-1} A_r P^C I_r + \sum_{m=1}^{M} D_m + TB.
\]

Finally, arbitrage on the financial markets equalizes net returns on financial assets. The net return for holding capital in firm \( v, r \) is \((r^k_r - \delta_k) P^C_r + (1 - \delta_k) \Delta P^C_r\). Firms are symmetric and hence \( r^{k,v} = r^k_r \) for all \( v \). Letting \( r_{G,m} \) denote the return on government bonds of country \( m \) and \( r_F \) the return on foreign bonds, the arbitrage condition is

\[
(r^k_r - \delta_k) P^C_r + (1 - \delta_k) \Delta P^C_r = r_{G,m} = r_F
\]

for all \( m = 1 \ldots M \) and for all \( r = 1 \ldots R - 1 \). Note that the required gross return for physical capital \( r^k P^C \) is higher in regions where the price of capital \( P^C \) is high. This reflects the fact that depreciation incurs a higher financial loss when the resources needed to acquire capital are more important, which is for instance the case in remote regions.

Households hold assets in proportion to their saving. The accumulation of assets by household \( h, q \) is then described by the following law of motions:

\[
\Delta P^{k,v} = \frac{S_{h,q}}{S} \Delta q_{v,r},
\]

\[
\Delta B^{C} = \frac{S_{h,q}}{S} D_m,
\]

\[
\Delta B^{F} = \frac{S_{h,q}}{S} TB
\]

where \( S = \sum_{q=1}^{N} \sum_{h=1}^{H} S_{h,q} \) corresponds to the total savings of domestic households.
6 Location and spatial equilibrium

6.1 Why does space matter in RHOMOLO?

The model breaches a number of the conditions identified by Starrett (1978) for having perfectly homogenous distribution of economic activity in space. In particular, agents and factors of production are partly immobile, locations are not uniforms (because population and accessibility varies from one region to the other), the economy is open, there is imperfect competition on product and labour markets and the introduction of knowledge spill-over makes some markets incomplete. There are however two sets of elements without which the issue of location and space would not exist in the model: the combination of trade cost and increasing returns on the one hand, and the combination of knowledge spill-over and localised externalities on the other hand.12

Both consumers and producers face positive trade costs for importing final/investment goods and intermediate inputs. On the consumer side, trade costs enter the consumer price index (6). On the producer side, trade costs enter the intermediate goods price index (12) and the investment price index (similar to the consumer price index). However, departing from the standard framework of the new economic geography literature, bilateral trade costs between regions are assumed to be asymmetric and the internal trade costs to be positive. Values for the inter-regional trade costs come from the data, instead of being calibrated or proxied by distance (see Potters et al. 2013; Thissen et al. 2014, for details).

Increasing returns to scale are introduced via fixed costs in firms production functions (10) and (22). Following Venables (1996), they are made of part of the firms output. In contrast to trade costs, fixed costs is strictly speaking an exogenous variable rather than a parameter. Nevertheless, they can be used to calibrate the model.

The combination of increasing returns – preventing the endless division of the scale of economic activities and hence the emergence of so-called backyard capitalism – and of transport cost – without which the issue of space would be irrelevant – makes access to large markets a determinant of the firms performance. Access to large markets allows the exploitation of economies of scale and hence increase profits. Location (close to a large market) then becomes a decision variable.

Localized externalities enter RHOMOLO trough technological and knowledge spillovers whose scope is assumed to be limited in space to the boundary of the region. Indeed, localized externalities are region-specific and determine the relationship between the density of workers and durable goods firms in a region on the one hand and the performance of the local durable goods sector and hence the productivity of factors on the other hand. When the number of durable goods firms increases in one region, the total productivity of factors used in the industry also increases. This leads to an increase in the number of firms in the final goods sector which in turn increases demand for durable goods and hence profits in the durable goods sector. This type of Marshallian externality (see for instance Marshall 1890 or Scitovsky 1954) implies that R&D and technological progress tends to be spatially concentrated in a limited number of places.

6.2 Spatial equilibrium

In the short run, pure profit may exist. However, in the long run, this will trigger the entry of new firms on the market which will decrease the demand addressed to each firm and hence reduce the

---

12 See Di Comite and Kancs (2013) for a detailed description of agglomeration and dispersion forces and mechanisms in RHOMOLO.
level of profit. This process takes place until pure profit is completely exhausted. The profit of firm \(i, s, r\) reads

\[
\pi_{i,s,r} = p_{i,s,r} X_{i,s,r} - P^{y}_{i,s,r} y_{i,s,r} - \sum_{u=1}^{S} P^{u}_{r} X_{i,s,r}^{u} - p_{i,s,r} (FC_{i,s,r} - Sub_{m}^{i,s,r} - Sub_{EU}^{i,s,r})
\]

\[= p_{i,s,r} X_{i,s,r} - P^{y}_{i,s,r} X_{i,s,r} - \sum_{u=1}^{S} a_{s}^{u-1} P^{u}_{r} X_{i,s,r}^{u} - p_{i,s,r} (FC_{i,s,r} - Sub_{m}^{i,s,r} - Sub_{EU}^{i,s,r}). \tag{29}\]

Pure profit is equal to zero when the price equals average cost, namely,

\[0 = p_{i,s,r} - P^{y}_{i,s,r} - \sum_{u=1}^{S} a_{s}^{u-1} P^{u}_{r} X_{i,s,r}^{u} - p_{i,s,r} (FC_{i,s,r} - Sub_{m}^{i,s,r} - Sub_{EU}^{i,s,r})/X_{i,s,r}. \tag{30}\]

Using the price setting rule (11), one obtains the level of production corresponding to zero profit:

\[X_{i,s,r}^* = FC_{i,s,r} - Sub_{m}^{i,s,r} - Sub_{EU}^{i,s,r}/1 - \theta.\]

The same mechanism applies to the durable goods sector. For each firm in the sector, pure profit is exhausted when demand is such that the price it sets is equal to average cost:

\[p_{v,s,r} = r^{k}_{r} P^{c}_{r} + P_{j,m} / z_{v,s,r} + (FC_{v,s,r} - Sub_{m}^{v,s,r} - Sub_{EU}^{v,s,r})/z_{v,s,r}.\]

By Equation (24), the price is a mark-up over marginal cost which, combined to the expression above, gives the production level which annihilates pure profit:

\[z_{v,s,r}^* = P_{j,m} + FC_{v,s,r} - Sub_{m}^{v,s,r} - Sub_{EU}^{v,s,r}/\rho \cdot \frac{1-p^{c}_{v}s_{r}^{c}}{1-\rho^{k}_{v}s_{r}^{k}}.\]

We then have a system of \(s \times r\) equations of the type \(X_{i,s,r}^* = D_{H}^{i,s,r} + D_{F}^{i,s,r} + D_{K}^{i,s,r} + D_{G}^{i,s,r}\) plus \(r\) equations \(z_{v,s,r}^* = D_{F}^{v,s,r}\) with \(s \times r + r\) unknowns corresponding to the long term number of firms in each sector and in each region, \(N_{s,r}^*\) and \(A_{v}^*\).

Transition to the long term number of firms is not immediate and is described by the following law of motion, which is assumed to be the same in every region and sector: \(\Delta N = \lambda \cdot (N - N^*)\). The number of firms in each region determines the spatial distribution of economic activity in the model. It is fully endogenous and incorporates several agglomeration and dispersion forces.

6.3 Agglomeration and dispersion forces

Four effects drive the mechanics of endogenous agglomeration and dispersion of economic agents in RHOMOLO: the market access effect, the price index effect, the market crowding effect and the localized externalities effect.

\[\text{The expressions describing total demand are relatively complicated but one can indeed show that it is a decreasing function of the number of firms. In the simple case where there is only one sector and one region, the demand addressed to a particular firm by consumers is }\frac{1}{N} \cdot \frac{I}{p}\text{ where }I\text{ is the income devoted to consumption.}\]
The market access effect is based on the fact that, due to the presence of increasing returns and transport costs, firms in large/central regions tend to have higher profits than firms in small/peripheral regions. Firms therefore prefer to locate in large/central regions and export to small/peripheral regions. Due to positive trade costs, the demand for a region’s output increases with its relative accessibility and its economic size. This can be seen in Equations (5), (15), (23) and (26), according to which total demand addressed to firm \( i, s, r \), and hence its profit decreases with trade costs, \( \tau_{s,r,q} \), decrease with an elasticity \( \frac{1}{1-\theta} \). The weighted average trade costs can be lower either due to large internal market (low value of \( \tau_{s,r} \)) or due to good accessibility of/central location of a region (low value of \( <\tau_{s,r,q} \)), or both.

The profitability of firms facing larger demand is enhanced due to the existence of increasing returns, as growth in output reduces the average production costs. This can be seen by combining Equations (9), (10) and (29), according to which an increase in output, \( X_{i,s,r} \), reduces the share of fixed costs in average costs, and hence increases the firm’s profit.

The price index effect describes the impact of firms’ location and trade costs on the cost of intermediate inputs and of durable goods for producers of final demand goods. This follows the vertical linkage framework of Venables (1996). Large/central regions with more firms import a narrower range of products, which reduces trade costs. Therefore, intermediate inputs are less expensive in large/central regions than in small/peripheral regions. This can be seen in the intermediate inputs price index (12) which decreases in trade costs with elasticity 1. This suggests that that total trade costs, \( \sum_{r=1}^{R} \tau_{s,r,q} \), and hence the cost of production is lower in large/central regions. Moreover, production costs are also lower in regions with a large number of durable goods firms. Indeed, one easily checks that the durable goods price index (13) decreases with the number of durable goods firms \( A_r \). Because of lower production costs, firms purchasing intermediate inputs and using durable goods as a factor of production would prefer to locate in large/central regions.

The market crowding effect captures the fact that, because of higher competition for input and output markets, firms prefer to locate in small/peripheral regions with fewer competitors than in large/central regions where competition is fiercer. Indeed, when the number of firms in large/central regions increases consumption of differentiated goods is fragmented over a larger number of varieties, implying that each firm’s output and profit decreases. Given that the entry of new firms has a negative effect on profitability of incumbents in large/central regions, this market crowding effect works as a dispersion force.

The effect of competition on output markets can be seen in Equations (5) and (6), according to which the demand of output produced by firm \( i, s, r \) is decreasing in the number of final goods firms. Lower output, and hence profit, gives the incentive to firms to move away from large/central regions to small/peripheral regions with fewer competitors.

The effect of competition on input markets works through prices of spatially immobile production factors, namely labour and durable goods. Agglomeration of firms in large/central regions bids up prices for such production factors which reduces the incentive to locate in places where the number of firms is large.

The local externalities effect works through the probability to succeed in transforming designs into a new production process, \( \phi_r \), which depends on the pre-existing regional stock of durable goods firms, \( A_r \), and the stock of human capital, \( HC_r \) (see Equation 21). In particular, the probability to operationalize a new design is higher in regions where the number of durable goods firms is large. As a result, the accumulation of technology is facilitated in regions largely endowed with durable goods firms, creating the conditions for R&D and technological progress to agglomerate in places where the stock of knowledge and of technology is already large.
Table 2 summarizes the endogenous location mechanisms which drive the geographical distribution of final goods and durable goods firms and foster their agglomeration or dispersion in space.

Note that the agglomerations of final goods and of durable goods firms reinforce each other. A large number of final goods firms means a large market for durable goods firms which enhances the market access effect for the durable goods sector. A large number of durable goods firms implies that a large number of varieties of durable goods are available for final goods firms which enhances the price index effect for the final goods sector.

7 Data and empirical implementation

7.1 Dimensions of RHOMOLO

RHOMOLO covers 267 NUTS 2 regions in EU 27, which are disaggregated into 6 NACE Rev. 1.1 sectors (see Table 3 and Figure 3, respectively). The detailed regional and sectoral disaggregation imposes significant data requirements. In particular, the empirical implementation of the RHOMOLO model requires data for all exogenous and endogenous variables at regional (and sectoral) level for the base year (2007), and numerical values for behavioural parameters.

The base year (2007) data are compiled in form of an inter-regional social accounting matrix (SAM) (see Potters et al. 2013; Thissen et al. 2014, for details). For the construction of all EU 27 countries’ SAMs, data from the World Input Output Database (WIOD) have been used. The WIOD database provides international input-output tables, International and national supply and use tables, national input-output tables, and socio-economic and environmental accounts covering all EU 27 countries and 13 other major regions in the world for the period from 1995 to 2009. An important advantage of the WIOD data is that re-exports are subtracted from the direct exports to calculate the final value of exports. Generally, the WIOD data are available for 59 NACE Rev. 1.1 sectors, which for the purpose of the present study are aggregated into six macro-sectors (see Table 3). First, the SAMs are constructed at the national level, and then regionalised by taking into account all available regional and sectoral data constraints, such as, regional data on value added, employment and other regional and sectoral information from EUROSTAT (see Potters et al. 2013 for details).

7.2 Data for inter-regional variables

Inter-regional labour migration is captured as net changes in the regional labour force (see Brandsma et al. 2014, for details). The net aggregate relocation of workers between any two regions is a function of the expected income and distance, which requires data for labour...

Countries and regions in RHOMOLO

Notes: The number of NUTS 2 regions in each country are in parentheses.

Fig. 3. Spatial disaggregation of the RHOMOLO model
migration, regional GDP and unemployment and migration elasticities. EUROSTAT’s Regional Migration Statistics dataset provides data on within country migration. The key statistics on migration in OECD countries provides data on international migration. The Household Income and Active Population data is also extracted from EUROSTAT. Finally, data on region- and sector-specific unemployment and wages is micro-estimated based on the EUROSTAT’s Labour Force Survey (LFS).

Inter-regional trade flows are estimated using inter-regional traffic counts data from Thissen et al. (2013) and is described in Thissen et al. (2014). This data is harmonized with the available macro-constraints from RHOMOLO’s SAMs: the distribution of production and consumption over the EU regions to ensure consistency with the country level trade flows data from the COMEXT international trade statistics, and the rest of RHOMOLO’s data. Inter-regional trade costs come from the TRANSTOOLS database.

7.3 Data for inter-temporal variables

Knowledge capital enters RHOMOLO through region-specific R&D intensities (innovation expenditures), which are available at the regional level from the EUROSTAT’s Science and Technology Indicators database. Whereas R&D data by sector are available at the national level, comparable data are not available at the regional level for most of the countries. In order to regionalize the national R&D data by sector, we use the EUROSTAT’s database, which distinguishes four sectors of performance – namely governments, higher education institutions, business sector and private non-profit organisations. Most of RHOMOLO sectors fall under the broader business sector. In a second step, we correct for the sectoral disaggregation by using the regional gross fixed capital formation by NACE sector. In this way we are able to construct the best available proxy for NACE sector R&D spending at the regional level – given the current availability of data.14

The regional stock of human capital is proxied by 3 levels of education: low skill (isced0_2), medium-skill (isced3_4), and high skill (isced5_6). Wages are differentiated on the basis of education levels, in order to allow for internalisation of investment decisions of households on the amount of education to be invested in each period. Data for this come from the LFS and the EU KLEMS database.

The regional stock of physical capital is constructed according to the perpetual inventory method (PIM), because comparable data for all EU 27 countries on capital stock at the regional/sectoral level of disaggregation are not available from any statistical data source. This approach takes the initial stock by country and industry (regionalized by gross value added (GVA) share) in the year 1995 and calculates the final capital stock by region and industry in 2007 by adding the yearly capital investments and depreciating the existing stock every year. We used the following data: gross fixed capital formation on NUTS 2 level and by sector in current prices for the years 1995–2010; price deflators for converting into constant prices; initial stocks for calculating the net capital stocks for each year applying the PIM from the EU KLEMS database. These data are available at the national level, but regionalized by the GVA share; depreciation rates (calculated by weighing the average service life of each of the six types of assets, using the EAS95 classification).

---

14 Currently undergoing extension of the innovation module in RHOMOLO with additional features beyond R&D includes two elements. First, European Commission-based regional patent statistics and citations offer valuable information on technological proximity across regions in Europe. Second, the inclusion of the micro-estimated data from the Community Innovation Survey is used to identify a broader set of regional innovation features – closely related to the policy domains identified in the current taxonomy of cohesion policy investments.
7.4 Model parameters

In order to parameterise the RHOMOLO model, all key structural parameters are estimated econometrically. For example, all parameters related to the inter-regional labour migration are estimated in a panel data setting for each country (Brandsma et al. 2014; Persyn et al. 2014). Second, all parameters related to the elasticities of substitution both on consumer and producer sides are being estimated based on micro-data. In the current version of RHOMOLO, the implemented elasticities of substitution are uniform for all sectors and regions. However, in future versions of RHOMOLO, they will be estimated by sector and region based on region and sector-specific micro-data. The missing behavioural parameters are drawn from the literature (Okagawa and Ban 2008).

Finally, as usual in CGE models, all shift and share parameters are calibrated to reproduce the base year (2007) data in the SAMs. In order to determine the sensitivity of simulation results with respect to the implemented parameters in RHOMOLO, we perform extensive sensitivity analysis and robustness checks. Among others, the sensitivity analysis allows us to establish confidence intervals (in addition to the simulated point estimates) for RHOMOLO’s simulation results.

8 Conclusion

Cohesion policy shifts the spatial equilibrium at the regional level within the EU and the Member States by increasing the capacity for growth in the regions that are lagging behind and to some extent also by mobilising the unused capacity in other regions. It does so by supporting investments in the transport infrastructure networks connecting the regions as well as by stimulating measures fostering the development of human resources, research and innovation and, in general, improving the standard of living and attractiveness of the regions. Although the room for public funding and redistribution is limited by balanced budget requirements, the impact on the less developed regions can be very substantial if the forces of agglomeration and dispersion of economic activity, as they are laid out in the new economic geography literature, are taken into account.

This paper presents the current version and proposes future extensions of the newly developed dynamic spatial general equilibrium framework in which the interplay of agglomeration and dispersion forces, including the ones set in motion by cohesion policy can be analysed in a novel and theoretically consistent way, including the impact in the net contributing Member States. Particular attention is paid to income and capital movements within and between regions that are generated by the stimulus to the regions. This will allow an assessment of the feedback to the Member States and regions and the possibility that in the longer run they will all benefit from the additional growth that is generated.

Turning to limitations, a general problem of the adopted dynamic spatial general equilibrium approach is that almost all model data is used for calibration, whereas very little data is left for testing the model. Hence, a promising area for future research is to estimate dynamic spatial general equilibrium models instead of calibrating them. In particular, the estimation and testing of large dynamic spatial general equilibrium models, such as RHOMOLO, is still an open issue to be addressed in the future.

Our approach has important implications for future research. First, in presence of multiple asymmetric regions and multiple endogenous channels of transmission, we point to the infeasibility of solving the model analytically. Second, the RHOMOLO model shows that a thorough modelling of the spatial interactions between agents can prevent the system from reaching corner solutions in spatial equilibrium. Finally, our results advocate more research to be devoted to the uniqueness and stability of spatial equilibrium in empirically implemented new economic
geography models with multiple asymmetric regions and multiple endogenous channels of adjustment. In this context, a particularly promising avenue for future research is saddle path stability and local properties around the steady state.
