UniversAAL project

UniversAAL is a European research project that aims at creating an open platform and reference specification which will make it technically feasible and economically viable to develop Ambient Assisted Living solutions. The project follows an open source license model; preliminary results are already available. The universAAL platform is built around three pillars: the runtime support, a set of software components that can be installed on different types of hardware used in an AAL environment; the developer support, a set of tools and guidelines to develop AAL services in accordance to a common reference architecture; and finally the community support built around the concept of uStore, a shop where end users (elderly and their care providers) can find complete AAL services, including all necessary software, hardware and human resources.

An overview of these concepts is provided with the help of videos and dissemination material at the UniversAAL booth. There you can know how to get in touch with the developers of universAAL, which are interested in knowing your specific requirements and get your feedback: this is the right time to influence the UniversAAL development!
